The six essays are entitled: "The Physician"; "Convalescence"; "Pain and its Consequences"; "The Moral Management of Invalid Children"; "Nervousness and its Influence on Character"; "Outdoor and Camp-life for Women."

Photographic Illustrations of Skin Diseases: an Atlas and Text-Book Combined. By GEORGE HENRY FOX, A.M., M.D. Complete in twelve parts. Second Series. New York: C. B. Treat, No. 771 Broadway.

The first two parts of the second series of Dr. Fox's well-known photographic illustrations of skin diseases, colored by hand, contain representations of seborrhœa, erythema multiforme, erythema exfoliatum, erythema bullosum, variella, variola, urticaria, urticaria pigmentosa, dermatitis caloricæ, dermatitis venenata, and erythematous eczema. They are undoubtedly the best photographic representations of skin diseases which have yet appeared, and the cases portrayed have been selected with care from a large amount of clinical material.

We do not, however, share in the opinion that the photographic process is the one best adapted to give a good picture of cutaneous pathology. The distribution and grouping of cutaneous eruptions are, of course, recorded with exactness, but the morphology and color of the individual lesions are not shown with the clearness and accuracy needful for purposes of instruction, and which may be better exhibited by a good lithographic reproduction of life-size paintings in water-colors. This is more particularly true of photographs like those of Dr. Fox, in which the representations are, as a rule, much less than life-size, and the individual lesions correspondingly small. Indeed, the two best plates in the above list are the two which approach most nearly to life-size; namely, those representing seborrhœa and erythematous eczema. In many of the others the special characteristics of the separate lesions are not exhibited with sufficient distinctness to be apparent, and the small size of the photographs also renders the proper application of color almost an impossibility. The accompanying text furnishes a concise account of the various diseases, together with directions for treatment.

¹ A more complete account of the explorations which furnish the basis of this report may be obtained from the *Boston Herald*, November 5, 1886; also from reprint from the *Johns Hopkins University Circulars*, Vol. 1, No. 49, Baltimore, May, 1886, p. 89.

Parts three and four contain examples of eczema rubrum et squamosum, squamous eczema, intertriginous eczema, facial eczema in children, eczema of the bearded face in adults, scyris non parasitica, trichophytosis barbe, squamous eczema of the palm of the hand, squamous syphilide of the sole of the foot, dermatitis exfoliativa, and psoriasis guttata. They are admirable photographs, and give good general pictures of the diseases represented. The effect produced, however, resembles somewhat that of seeing a patient at such a distance, that, although the general appearance of things may enable an expert to make a diagnosis, the nicer distinctions of form and color necessary to a decision in doubtful cases are not obvious. As in the plates contained in the first two parts, the best representations are those which are the nearest to life-size.

G. H. T.

The Vermont Asylum for the Insane. Its Annals for Fifty Years. Brattleboro: Printed by Hildreth & Fales. 1887.

This handsomely printed volume of three hundred pages has been carefully compiled from old asylum reports and other sources by the present superintendent, Dr. Joseph Draper.

The period of time covered embraces the most important events in the history of lunacy, and a continuous chronicle like this is valuable for purposes of historical reference apart from its value as a history of the foundation and development of a great institution of which Vermont may well be proud.

It appears that Mrs. Marsh, who died in 1834, appreciated the needs of the insane, saying that "nobody cared for the poor insane; they were neglected and shifted about, and she wanted to provide a home for them." She accordingly left ten thousand dollars in her will which was to be used to erect and support an insane hospital.

In 1835 the asylum was incorporated, there being at that time but ten other institutions of any size devoted to the care of the insane in the United States. But three of these were in New England; namely, the McLean Asylum, the Hartford Retreat, and the State Lunatic Asylum at Worcester.

On the 12th of December, 1836, the first patient was received, and thirty-four were remaining at the end of the first year. From this small beginning the asylum has gone steadily and prosperously on, until at the date of its report in 1886 it was able to accommodate four hundred and fifty patients, and owned property valued at upward of four hundred thousand dollars.

Practical Microscopy; A Course of Normal Histology for Students and Practitioners of Medicine. New York: WILLIAM WOOD & Co. 1887. 8vo. p. 217.

Miller's Microscopy does not differ essentially from other elementary treatises on histology intended for the use of medical students. It gives a brief account of the microscope and methods of making sections, etc. The greater part of the work is devoted to histology, the successive sections take up tissues and organs in the usual order, and in each case there is first given a brief general description and then directions for practical demonstration. The illustrations are nearly all original, being photo-engravings from the author's own pen drawings, the descriptions and directions are brief and in some respects good. We wish it were

possible to commend the work more liberally, for the author has evidently worked out the subject for himself, and is more than a mere compiler. Such an effort to be fresh and independent, deserves recognition and acknowledgment, unfortunately we are deterred from giving the praise it would be pleasant to bestow, because the standard of accuracy followed in this work is much lower than ought to be the case in a scientific text-book. Take, for instance, diagrams, Figures 69, 85 and 87, the first is intended to show the structure of the lungs, the second that of the kidney, the third that of the bloodvessels in the kidney; they are all three very misleading. The enlargement of the air-passages in the lungs is fundamentally different in nature from the arrangement shown in the figure. Figure 85 is a diagram showing the plan of structure of the human kidney. It is grossly inaccurate; the shape of the pelvis is imagined, and the medullary rays widen toward the outside; there are large spaces in the cortex without any rays at all. The cortical columns there represented have no existence anatomically, and inasmuch as it is especially characteristic of the medullary regions to contain no Malpighian capsules, it is curious to find them shown there in Dr. Miller's figure. Figure 87 purports to be after Ludwig's well-known figure in Stricker's handbook (Figure 150, page 500 of German edition), but of this it is a mere travesty.

Again, in Figure 121, representing a section of the spinal column, the neuroglia of the posterior horn is designated as the root of the nerve, and the root itself is not represented. The figures drawn from preparations, though better than the diagrams, leave a great deal to be desired; thus, in Figure 122 of the spinal cord, the characteristic and important differences in size and distribution of the nerve-fibres is not shown. In Figure 126, a section of the cerebellum represents the Purkinje's cells and their branches as quite different from the actuality. In some cases, as, for instance, Figure 53, the author has not drawn the cells according to the preparation, but like imbricated scales, as is evident at a glance at the cells above and below the layer of prickly-cells. Within the limits of accuracy which satisfy our author, he renders his descriptions and directions succinct and clear; but even in these respects his work ranks below Stöhr's "Histology," which still remains the best short manual known to us in any language.

A Hand-Book on Diseases of the Skin with Especial Reference to Diagnosis and Treatment. By ROBERT LIVESG, A.M., M.D., Cantab. F.R.C.P., London. London: Longmans, Green & Co., 1887.

This is an excellent little book and one well adapted for its purpose, that of giving a short account of the main points in the diagnosis and treatment of diseases of the skin. The style is good, the differential diagnoses well-put and the directions for treatment sensible. It is a "hand-book" to be recommended.

G. H. T.

— Mr. T. B. Curling whose name is well known in connection with his work on the Testis and Rectum, died at Cannes on March 4th. Perhaps the most important of his original observations was the discovery of the association of ulcers of the duodenum with burnus on the skin.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 22, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

HYPERTROPHY OF THE HEART CONSECUTIVE TO NERVE LESIONS.

POTAIN, in a recent clinical lecture, reported in the *Semaine Médicale*, gives the details of several cases of hypertrophy of the heart following painful lesions of the brachial plexus. One of the patients was a soldier, whose left arm had been amputated for an injury received in the late Franco-Prussian War. This patient long suffered from pain in the stump, from numbness and contracture. A neuroma developed over the median and ulnar nerves; the pain and other morbid symptoms were traced to this. There had long been palpitations of the heart and other disturbances of this organ; the heart was also found to be markedly hypertrophied. The precordial dulness measured 160 square centimeters, and the apex-beat was found in the sixth interspace; all signs of valvular lesion and of kidney trouble were wanting. Expiration of the neuroma for a time brought complete alleviation of all the morbid nerve-phenomena, with removal of the cardiac disorders; afterwards there was a return of the old troubles, which eventually disappeared after several *séances* of galvanization of the brachial plexus.

Another case was that of an officer who had been wounded in battle by a shell, an accident which necessitated amputation of the left arm. A neuroma developed in the stump, attended with painful irradiations and a notable hypertrophy of the heart. Resection of the tumor, a course of treatment by the bromides, and a season spent at Baguères resulted in a complete cure.

A similar case appears in the reports of the Hôpital Necker for 1881, and Lasègue, in his treatise on reflex cardiopathies of brachial origin, published in 1883, reports the case of a patient of Dr. Caizergues, of Montpellier, who had brachial neuralgia and cardiac hypertrophy consecutive to a neuroma of the left arm; amputation of the tumor restored the patient to health. Potain quotes from Dr. Weir Mitchell a similar case following a gun-shot wound, in which the ulnar nerve was involved. Instances of a like nature seem now to be sufficiently numerous.

Potain, after considering many possible explanations, concludes that the mechanism of the hypertrophy is as follows: the reflex irritation, starting from the brachial plexus, determines a diminution of resistance in the walls of the heart, which passively gives way during diastole. The heart undergoes constant distension and hypertrophies in consequence of the extra effort required to expel the contents, which are now spread over a larger surface than natural.

The prognosis may be regarded as favorable, all the inconvenience resulting from the hypertrophy, and even every trace of hypertrophy itself disappearing with removal or suspension of the distant source of irritation.

ANTIPIRYNE IN THE TREATMENT OF CHOREA.

LEGROUX has communicated to the Academy of Medicine, Paris, the results of his treatment of chorea by antipyrine. He claims remarkable success, affirming that by the administration of antipyrine he has been able to reduce to a period of from one to three weeks (many of his cases getting well in a week), the duration of a disease which ordinarily lasts from sixty to ninety days.

His treatment is as follows: One gramme (fifteen grains) of antipyrine is dissolved in twenty grammes (five drachms) of syrup of bitter orange peel, and the whole is administered at one dose. Three such doses are given during the twenty-four hours. He considers it perfectly safe to give this dose to a young child, and all of Legroux's patients are now treated in this way.

Legroux believes that antipyrine acts "by slowing the oxidations in the nerve-centres, moderating nervous excitability, and enhancing the elementary nutrition." By its sedative action on the spinal cord, it has proved of use in the convulsions of strychninism, and recently Lemoine has shown that some cases of epilepsy have been markedly benefited by antipyrine.

AN ENGLISH JUDGE'S IDEAS OF INSANITY.

DR. MERCIER reports in the *Lancet* of March 3d an extraordinary case of judicial obtuseness or perverseness: A young epileptic blew out his sister's brains with a discharge from a double-barrelled gun, and slightly wounded himself with two shots from the same gun. He then threw himself down two flights of stairs and into a fireplace. On application of his friends, two medical men were called to examine him, of whom one was the physician and superintendent of an insane asylum, and they reported that the young man was undoubtedly insane. The counsel for the crown declined to call the two medical witnesses, and when they were put on the witness-stand by the prisoner's counsel, the judge refused to allow them to state their qualifications as medical experts, and even declined to allow them to give their opinions as to the

soundness or unsoundness of mind of the youth. The judge would permit them to state only facts which they had observed, and, as they could not remember their exact conversation verbally with the prisoner, they were not permitted to place before the jury any indication as to their opinion of the case. The prosecuting counsel was strongly condemnatory of the prisoner in his speech, and the judge, in his summing up, even more so; but the jury, although not allowed to hear expert evidence, brought in a verdict of insanity.

In speaking of his countrymen, a distinguished diagnostician in London has called primary mental deterioration the "judge's disease." The first ruling in the present case was that the medical men could testify to only facts, and not to opinions, as they were called by the counsel for the defence, and not by the crown. It was also ruled that the prisoner was sane if he knew the nature and quality of the act that he committed, and understood that it was wrong, and that a verdict of "guilty, but insane," could not be returned unless the jury found that the prisoner, at the time of the crime, was suffering from a delusion such that if the facts had been as he deludedly believed them to be, he could legally have committed the act for which he was tried.

A demented epileptic of twenty-one commits murder because he has been treated so badly by "that beast, his sister Constance, that he must put an end to her life by shooting," to use his own words, and then tries to kill himself, knowing that the penalty for murder is hanging. In a note, found in his pocket, he says: "Good-by to all, hoping you will all have a happy time of it. Good-by, dear father and mother." The only complaints made against his sister were that she had not given him a newspaper when he asked for it, and that she had passed him in the street without speaking to him.

Fortunately, the jury could not doubt such evident marks of insanity, even without expert testimony, in spite of the judge and the counsel for the government. Even the short delay in giving their verdict was caused by a discussion whether or not to return to the court-room and demand to hear the opinion of the physicians as to the sanity of the prisoner.

THE EXECUTION OF CRIMINALS.

At a meeting of the New York Medico-Legal Society, held March 14th, a committee, consisting of Drs. R. Ogden Doremus, J. Mount Bleyer, Charles F. Stillman, Messrs. Clark Bell and Frank H. Ingram, made a report in regard to the best method of executing criminals which reaches quite different conclusions from that of the Society of Medical Jurisprudence noticed in our last issue. A portion of the report was as follows:

That the provisions of our Constitution "that cruel and inhuman punishment shall not be inflicted" should be enforced by appropriate legislation, and all

existing statutes repugnant to either its letter or spirit be repealed. That hanging should be abolished as cruel and contrary to the public sense of our civilization. That as a substitute for the present death penalty, we would recommend: (a) death by the electric current; or (b) death by hypodermic or other injection of poison; or (c) death by carbonic oxide gas injected into a small room in each jail, as recommended by Prof. John H. Packard (Medico-Legal Papers, Vol. III, p. 521), giving our preference to the first, or death by the electric current. That in our judgment executions should be private, and not public. That if it were possible to prevent the publication of details of executions in the public press, it would be a public good. That the bodies of criminals should be delivered to the medical schools, after execution, for dissection.

This report, which was adopted by the Society, is intended to be limited to the subjects embraced in the report now before the Legislature, and it expresses the opinion that the commissioners who prepared the latter are entitled to the thanks of the Legislature and the public for the able and exhaustive labor they have bestowed upon the matter.

MEDICAL NOTES.

— A Committee of the Trustees of the Johns Hopkins Hospital, at Baltimore, is to visit Boston and New York next week in order to inspect the hospitals of those cities.

NEW YORK.

— The Legislature has appropriated \$185,000 for the erection of a new State asylum for insane criminals, which is to be located near Fishkill village, in Dutchess County, and will have in connection with it a farm of 246 acres. In addition to a central administration building, there will be six general pavilions, two infirmaries, and two isolated buildings planned especially for the most dangerous and violent class of cases. The plans for the various buildings, which will be of brick, with stone foundations, have been prepared by Capitol Commissioner Perry, of Albany, and it is designed to make the hospital a model institution of its kind.

— In the Section on Public Health, Hygiene, and State Medicine of the Academy of Medicine, on March 16th, Dr. C. L. Dana read a paper on "The Influence of Immigration on the Increase of Mental and Nervous Diseases." In 1880, he said, the percentage of our foreign-born population was over one-eighth of the whole nation. About one-quarter of the persons who are of an age susceptible of insanity are foreign born, and such persons furnish a little over one-quarter of our insane. Evidence exists showing a greater proportional mortality from nervous diseases in large cities among foreign-born adults than among natives. But, taking the entire population, the death-rate from all nervous diseases is much greater among natives, owing to the prevalence of such diseases

among children; while the direct influence of immigration in increasing nervous diseases is not great. Dr. Dana pointed out that implicit reliance could not be placed on the statistics which have been gathered in regard to insanity in this country, and his studies had led him to believe that it was wiser to treat the subject from a conservative point of view. The conclusion that he arrived at was that immigration tends to increase insanity indirectly through the influence of social life and through the introduction of poor nervous stock.

—The twenty-seventh annual commencement of Bellevue Hospital Medical College was held at the Carnegie Laboratory, March 12th, when a class of 144 was graduated.

—There were eleven graduates at the College of Veterinary Surgeons, which held its commencement exercises March 13th.

—The twenty-second annual commencement of the New York College of Dentistry was held at Chickering Hall, March 10th. There were 72 graduates, and the address to the class was delivered by the Rev. Dr. Thomas Gallaudet.

—The recent blizzard caused considerable delay in the removal of two small-pox patients from different sections of the upper part of the city, and on the way to the hospital, the sleigh containing one of them was upset in a snow-bank.

Miscellany.

THE LATEST THERAPEUTIC NOVELTY.

A CASE not less instructive than amusing is, we learn from an English contemporary, about to come to legal issue in London before long. Two years ago a London doctor had on his list of patients a lady long suffering from an affection of the face and jaw, which baffled the arts of the faculty. She changed her residence from London to a provincial town, but kept herself in the hands of her London doctor by letter. Finding the ailment obstinate, and the patient somewhat hypochondriacal, the doctor wrote in the end saying he had exhausted his resources, and adding his opinion that *Tempus edax rerum* was the only remedy. Straightway the lady hied herself off to a local chemist, and applied for the specific as set forth in the letter. The attendant, it will be contended, through deliberate dishonesty, made up a bottle for which he charged 7s. 6d., and at the patient's request registered her name as a customer to whom the remedy was to be regularly supplied. She continued using and paying for the sham medicine for over a year and a-half. Coming to London for the Jubilee, she chanced to meet her former doctor, who was astonished to find himself gratefully thanked for his invaluable prescription. He wrote at once for an explanation, and the next stage of the business began with the disappearance of the assistant, and the denial of any responsibility of the chemist, but, nevertheless, the case stands for trial. The plaintiff, has it seems, been an invalid from her twentieth year, and has paid for medicine alone over £2,000.

VIBURNUM PRUNIFOLIUM.

DR. AUVARD in the *Gaz. Hebdom.*, No. 31, writes of his observations regarding the action of viburnum prunifolium as follows: ¹

Three preparations of the drug are principally used, — the fluid extract, the soft extract, and the tincture.

Dr. Auvard's experiments were made with the tincture. This (one to five) can be given in doses of 100 to 150 drops in twenty-four hours. The active principle seems to be viburnin, which was first discovered by Van Hallen, but as yet it has not been experimented with. Indications for the use of viburnum in threatening abortion are the same as in the prophylaxis of the aborta. According to Auvard, the drug should not be used in the following cases:

(1) When the fetal membrane is torn and the water has been discharged. However, when during the sixth or seventh month of pregnancy there is a rupture of the membrane but there are still hopes of preventing a miscarriage, viburnum may be used.

Auvard cites a case of a young primipara, in the sixth month of whose gestation there was a rupture of the fetal membrane, and the woman had for five weeks been losing large quantities of amniotic fluid. The drug had been used all the while, and in consequence the woman was able to make a three hours' journey, and not until three hours later did she give birth to a living child.

(2) Viburnum should never be used if the fœtus is dead.

(3) When labor is well under way and the birth expected momentarily, or if a miscarriage has commenced.

(4) When the mother has a severe illness which contraindicates the causing of any delay in the birth.

Dr. Auvard cautions practitioners to abstain from using viburnum for severe after-pains until the uterus has been washed out.

In gynecology viburnum is valuable in dysmenorrhœa. It also has a highly beneficial effect on colic of the bowels accompanied by diarrhœa. Viburnum is preferable to opium in such cases for the following reasons: it is not toxic, it does not cause constipation, and its action is a more local one.

Viburnum does not seem to have any injurious effect on the stomach, and is always well borne.

Dr. Auvard advises the use of the drug in the following formula:

R. Tincturæ viburni prunifolii (1 to 2).
S. — 10 drops every hour until the pain has ceased.

INDEX MEDICUS.

It is a constant source of humiliation that the "Index Medicus" is not more widely supported. The following article from the *Therapeutic Gazette*, tells the present condition of the publication.

There is no profession in which the spirit of research and of literary activity, is as strong as it is in the medical profession. Indeed, according to our thinking, it would be better for the profession if its activity was somewhat checked; at least it would be much easier for those of us whose position requires that they should keep ahead or abreast of the ever

¹ See *Therapeutic Gazette*, February 15.

oncoming tidal wave. Some little time since we made a careful estimate, by going over a volume of the "Index Medicus," and found that in round numbers about fifteen thousand doctors had written books and articles on medical subjects in the year. These doctors probably averaged three articles apiece, and if unsigned and uncatalogued editorials, etc., are counted in, probably not much less than fifty thousand articles were cast adrift upon the waters of medical publication in 1885. It is a fair estimate that one out of thirty of these articles was worth reading by a serious man, and the labor of hunting out the good pieces of timber in the vast mass of drifting wood is certainly gigantic. Indeed, it would be impossible to do the thing satisfactorily at all were it not for such publications as the "Index Medicus." Of all keys of current medical literature that have been published since the world was, on this or any other planet, the "Index Medicus" is the most complete and the most satisfactory. To the literary doctor who has once used it, it has become as necessary as the morning cup of coffee or the evening meal, without which life is a burden, and effort a despair. The number of student physicians in any place can be fairly judged by the number of subscribers to the "Index Medicus." As a matter of curiosity we append the following list of paying subscribers in and out of the United States:

MEMORANDUM SHOWING THE NUMBER OF PAYING SUBSCRIBERS TO THE "INDEX MEDICUS."

very warmest thanks of the profession, but how long he will continue to carry this burden, we do not know. It is most extraordinary that he does not in this matter receive better backing. The thanks of the profession are good, but the thanks which do not express themselves in bank-notes are only an exemplification of the old proverb. "Soft words butter no parsnips."

SPASMUS NUTANS IN DENTITION.

DR. E. TORDENS' out-patient class in Brussels has been afforded the opportunity, as we learn from the *Lancet*, of seeing a case of spasmus nutans, or *tic de salaan*. This is not a very common affection, but several examples are mentioned by Henoch in his "Lectures on Children's Diseases." The Brussels case was that of a little girl of ten months, still at the breast. She had been very healthy, and was fairly robust. A month previously to her admission the mother had noticed a slight but nearly constant nodding motion of the head. When examined for the first time the chief motion was rotatory; the eyes also rolled from side to side, especially when the head was held. There were two teeth. The child was treated with oxide of zinc and bromide of potassium. The next time the patient was brought, a fortnight later, but little improvement could be detected, and a nodding motion was added to the lateral oscillation. Afterwards, however, improvement commenced, and at the end of six weeks from the first visit the child was quite well. By that time she had cut two new teeth. There could be little doubt that the affection was a complication, though a rare one, of dentition.

Correspondence.

THE COUNTRY PHYSICIAN'S ARMAMENTARIUM.

[THE following letter from a successful young physician in a prosperous country town, though not originally intended for publication, is published as it was written, in the hope that such a course may prove the best means of stimulating others to take up the subject as suggested by the writer and thus effect a profitable exchange of experiences.—Ed.]

March 12, 1888.

MR. EDITOR,—Since going into practice, my attention has been drawn a good deal to the matter of outfit: first, supplies at my office, and second, the contents of my bag and buggy.

As the success of a country physician in a given case at a given visit, depends, oftentimes, less upon his knowledge than upon the medicines and materials which he has with him to use upon the spot, it occurred to me that the matter of the physician's armamentarium might be an interesting and valuable one to discuss in the columns of the *BOSTON MEDICAL AND SURGICAL JOURNAL*. It would be especially so if the hints and customs of a large number of physicians could be drawn out. Every physician carries some particular preparation which he finds more convenient and suitable for a larger number of uses than other preparations of the same class. Likewise, others have some particular way of carrying or stowing away this or that instrument. Another selects his instruments in such a way that each one will serve for several purposes, on occasion. Others neglect to carry any instruments, thereby causing unnecessary trips over the road.

In addition to these, 100 copies are taken for distribution to the medical officers of the army at special rate, making 163 total.

In the home list it is curious to remark that New York has twice as many subscribers as Pennsylvania, and that in Massachusetts, Maryland, and the District of Columbia, a reading physician does not seem to be a very scarce animal. In the great State of Illinois, with the fermenting mass of commercial activity like Chicago, but eight doctors have had pride enough in their country's publication, interest enough in medical science, or a love of reading sufficient to warrant their spending ten dollars a year in sustaining the most illustrious medical publication in the United States, and nurturing their own souls and bodies by medical culture. Worse than this, a rich State like Kentucky, with cities as large as Louisville, does not even seem to require one copy of the publication.

The receipts from the "Index Medicus" to the publisher, are not nearly enough to cover the cost of so extensive a publication. Mr. Davis deserves the

I know several practitioners who carry only a medicine case, with no accommodations for instruments. I find it of much advantage to go well provided; to be able to give ether, apply an antiseptic dressing, extract a tooth, give an enema, etc., at a moment's notice when on the road. Were I less well-equipped, I should often have to make an extra trip, or deprive the patient of appropriate treatment.

This matter, of course, is of most consequence to country physicians, but cannot fail to have some bearing on city practice as well. It is, to a certain extent, a matter of

whims and perhaps no two practitioners would exactly agree as to the proper outfit. It is nevertheless important not only to the patient, but for the convenience of the practitioner. I write, merely to offer you the suggestion, so that you may, (if you think it wise and practicable), take some measures to draw attention to the subject in the JOURNAL, and if possible, to do so in such a way as to invite hints and individual contributions, which would be of value to many a country doctor.

Respectfully yours,

M.D.

Deaths reported 2,003: under five years of age 700; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 261, acute lung diseases 379, consumption 288, diphtheria and croup 108, scarlet fever 36, diarrhoeal diseases 31, measles 21, cerebro-spinal meningitis 20, typhoid fever 17, whooping-cough 9, erysipelas nine, malarial fever five, small-pox three, puerperal fever two. From measles, Washington 16, New York three, Milwaukee two. From cerebro-spinal meningitis, New York six, Philadelphia five, Worcester two, Boston, Washington, Nashville, Fall River, Lynn, Springfield and Taunton one each. From typhoid fever, Philadelphia five, Lowell three, New York and Lawrence two each, Washington, Pittsburgh, Milwaukee, Salem and Haverhill one each. From whooping-cough, New York three, Boston and Pittsburgh two each, Nashville and Somerville one each. From erysipelas, New York six, Nashville, Worcester and Somerville one each. From malarial fever New York five. From small-pox, New York two, Boston one. From puerperal fever, Philadelphia two.

Cases reported in Boston: Measles 11, scarlet fever 34, diphtheria 25, small-pox two, and typhoid fever two. In Milwaukee, scarlet fever 19, diphtheria 10. In Nashville, small-pox two. In Portland, measles two, diphtheria one.

In 19 cities and greater towns of Massachusetts with an estimated population of 1,047,570, the total death-rate for the week was 21.37 against 24.03 and 23.20 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending February 18th, the death-rate was 20.9. Deaths reported 3,764: infants under one year of age 797; acute diseases of the respiratory organs (London) 487, whooping-cough 170, scarlet fever 61, fevers 40, measles 38, diphtheria 35, diarrhoea 24, small-pox (Sheffield 30, Bristol and Leeds two each, London, Nottingham and Manchester one each) 37.

The death-rates ranged from 14.1 in Birkenhead to 29.4 in Wolverhampton: Birmingham 26.5; Bradford 15.4; Hull 16.5; Leeds 22.3; Leicester 19.2; Liverpool 21.8; London 20.6; Manchester 29.3; Newcastle-on-Tyne 20.0; Nottingham 18.8; Plymouth 24.2; Sheffield 24.7.

In Edinburgh 21.1; Glasgow 26.0; Dublin 25.9.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending February 25th, the death-rate was 21.6. Deaths reported 3,888: infants under one year of age 785; whooping-cough 173, scarlet fever 70, fever 43, diphtheria 40, measles 46, small-pox (Sheffield 20, Manchester five, Liverpool, Oldham, Blackburn and Leeds one each) 29.

The death-rates ranged from 13.0 in Cardiff to 32.2 in Plymouth; Birmingham 20.7; Blackburn 28.5; Bradford 17.0; Halifax 18.2; Hull 16.5; Leeds 18.6; Leicester 18.5; Liverpool 22.7; London 21.6; Manchester 25.4; Norwich 16.7; Nottingham 18.5; Sheffield 25.0.

In Edinburgh 21.1; Glasgow 27.0; Dublin 28.4.

The meteorological record for the week ending March 10, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 10, 1888, TO MARCH 16, 1888.

STERNBERG, G. M., major and surgeon. Ordered to proceed to Brunswick, Ga., on official business, and upon completion of same will return to his proper station. S. O. 57, A. G. O., March 10, 1888.

KEAN, JEFFERSON R., first lieutenant and assistant surgeon. Relieved from duty at Fort Still, Ind. Ty., and ordered for duty at Fort Robinson, Neb. S. O. 56, A. G. O., March 9, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MARCH 17, 1888.

RUSH, W. H., passed assistant surgeon. Detached from Navy Yard, New York, and to Naval Hospital, Philadelphia, Pa.

STEELE, J. M., passed assistant surgeon. Detached from Naval Hospital, Philadelphia, and to Coast Survey Steamer "Bache."

OBERLY, A. S., medical inspector. Detached from Navy Yard, Portsmouth, N. H., and wait orders.

DEBOIS, F. L., surgeon. Ordered to the Navy Yard, Portsmouth, N. H.

KEENE, JAMES, assistant surgeon. Ordered to the receiving-ship "Minnesota."

DEANE, C. W., passed assistant surgeon. Detached from Marine Rendezvous, San Francisco, and to Coast Survey Steamer "McArthur."

AUZAL, E. W., assistant surgeon. Detached from Coast Survey Steamer "McArthur" and to Marine Rendezvous, San Francisco.

BIDDLE, CLEMENT, passed assistant surgeon. Ordered to Naval Academy, Annapolis, Md.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING MARCH 10, 1888.

HUTTON, W. H. H., surgeon. To proceed to Brunswick, Ga., on special duty, March 5, 1888. Detailed as president of Board to select site for Gulf Quarantine Station, March 10, 1888.

CARTER, H. R., passed assistant surgeon. Detailed as recorder of Board to select site for Gulf Quarantine Station, March 10, 1888.

WASHIN, EUGENE, passed assistant surgeon. Granted leave of absence for thirty days. March 8, 1888.

BRAYTON, W. D., assistant surgeon. Ordered to examination for promotion. March 7, 1888.

SOCIETY NOTICES.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the Hall of the Roxbury City Guard, 67 Warren Street, Roxbury, March 27, 1888, at 7.45 P.M., Communications: "Temperament and Diathesis in Disease," F. B. Stevenson, M.D. "A Case of Appendicitis with Unusual Symptoms," C. A. Cheever, M.D.

S. ALLEN POTTER, M.D., Secretary.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT. — A Regular Meeting of the Society will be held Monday, March 26th, at quarter of eight, P.M. Reader, Dr. F. C. Knapp. Subject, "Nervous Affections following Injury, — Concussion of Spine, Railway Spine, and Railway Brain." Dr. J. J. Putnam will show two cases; Dr. F. C. Shattuck will show the Plasmodium Malariae; Dr. H. C. Ernst will show the Typhoid Bacillus and Sherrin's Cancer Bacillus.

F. B. HARRINGTON, Secretary.

CARTWRIGHT LECTURES FOR 1888.

The Cartwright Lectures of the Alumni Association of the College of Physicians and Surgeons of New York, for 1888, will be delivered at the College by Prof. Wm. H. Welch, of Johns Hopkins University, on Thursday evenings, March 29th, April 5th and 12th, at 8.30 P.M. The subject will be the "General Pathology of Fever."

DEATH.

Died in Dorchester, Mass., March 15, 1888, Francis Henry Mullen, M.D., M.M.S.S.

NOTES ON COMPLICATIONS MET WITH IN CASES OF STRANGULATED HERNIA.¹

BY A. T. CABOT, A. M., M. D.
Surgeon at the Massachusetts General Hospital and at the Children's Hospital.

It is the object of this paper to present an account of some of the complications met by the writer in the operation of herniotomy.

Some of these complicating circumstances have merely a scientific interest, while others introducing special danger, require operative measures for their relief and demand therefore, the consideration of surgeons.

HYDROCELE OF THE HERNIAL SAC.

J. L., a very stout laboring man of about forty, entered the Massachusetts General Hospital, December 23, 1885. He gave an indefinite history of an enlargement, as he supposed, of the left testicle coming on slowly in the past five years. He did not pay much attention to it till one month before entrance, when it began to be inconveniently large. One week ago, after a blow on the scrotum from the handle of a switch, it increased rapidly in size, and caused a severe dragging pain along the cord and up into the groin.

At entrance he had a tense elastic swelling somewhat larger than two fists, filling the left side of the scrotum, and extending up into the inguinal canal. The penis was almost wholly concealed. The tumor was not translucent.

An aspirating needle was introduced, and between one and two pints of reddish fluid were withdrawn. This only reduced the tumor about one-third, leaving still an elastic, but not tense, swelling extending from the bottom of the scrotum up into the inguinal ring. The fluid rapidly reaccumulated in the sac, and in about a fortnight the patient was etherized and an incision was made into the scrotum. A good quantity of bloody serum like that withdrawn by the aspirating needle was evacuated, and then the mass filling the scrotum behind was seen to be an omental hernia much altered in its appearance by edema, and studded here and there with spots of ecchymosis. The omentum was tied with silk at the constricted part in the neck of the sac and then cut off, the pedicle being returned to the abdomen. The ring was brought together as well as possible with sutures, a drainage tube was introduced into the old hernial sac, and the wound was closed around it.

Convalescence was slow, and was retarded by an abscess in the scrotum, but the wound finally healed solidly.

The condition which was found in this case is a rare one. Dr. McArdle and Dr. Kolpinski, in a recent paper,² have been able to find but twenty-nine authenticated cases of hydrocele of the hernial sac. They find that the accumulation of fluid may take place in a sac which at the time has no abdominal contents, but that the more common condition is an irreducible epiplocele with adhesions about the neck of the sac. Occasionally a small knuckle of intestine may partly protrude. Usually the antecedent history of hernia makes the diagnosis tolerably clear. In our case the

extremely meagre history which the closest questioning could not amplify, left us in doubt as to the nature of the previous swelling; and the recent injury with the bloody fluid led us to think strongly of an hæmatocele in an old hydrocele sac.

FEMORAL HERNIA WITH A DOUBLE SAC.

This patient is also interesting for having undergone two herniotomies within four months.

On March 24, 1887, Kate L., aged thirty-four, entered the Massachusetts General Hospital with a strangulated hernia at the left femoral ring.

She was operated upon by Dr. John H. Mians. Upon cutting down upon the hernia he opened a sac containing about two ounces of serum. During incision of the constriction a second sac lying against and covering the ring was punctured, and through the opening a probe passed into the abdominal cavity through the ring. This inner sac was pushed into the abdomen, and the ring was closed with catgut sutures.

Convalescence was somewhat retarded by an attack of erysipelas, but she was discharged well in less than a month.

On July 25, 1887, she again entered the hospital with a strangulated hernia at the same ring as before. She had worn a spica bandage for two months after leaving the hospital but then discontinued it. One week ago she again noticed a bunch in the groin, and twelve hours before entrance, while stooping to pick up something, she felt a "giving way" in that side. She soon began to suffer from abdominal pain and to vomit.

The tumor was about the size of a hen's egg. She was etherized, and gentle taxis proving unavailing, herniotomy was done. The dissection down to the sac was somewhat obscured by the cicatrix and adhesions following the previous operation. A sac containing about two ounces of serum was opened, and at the bottom of it was a bulging mulberry-colored mass, adherent around the ring. At first this was thought to be an adherent coil of intestine, but it was presently shown to be a second sac. This was now opened, and at the bottom of it was a little strangulated bit of intestine no larger than the end of the thumb. The constriction was divided, and this was returned to the abdomen. The neck of the inner sac was pulled down and tied, and also stitched to the sides of the ring. The outer sac was stitched together with the skin.

The recovery was uninterrupted. The bowels relieved themselves of flatus about twelve hours after the operation, and the patient went home on the seventeenth day.

INGUINAL HERNIA WITH HOUR-GLASS SAC.

J. M., aged twenty-nine, entered the hospital July 21, 1887. He had ruptured himself on the right side while riding two-and-a-half years before. The hernia was reduced by taxis, and a truss was worn. Three months ago the hernia came down again, and after a few days was reduced by recumbency and the application of ice.

Two days before entrance he carried a heavy valise some distance. The next day he felt some pain in the right iliac region, and vomited twice that evening. When seen at the hospital the right side of his scrotum was occupied by a soft elastic swelling as large as an

¹ Read before the Surgical Section of the Suffolk District Medical Society, Feb. 1, 1886.

² Phil. Med. News, Jan. 9, 1886.

orange. Over the inguinal ring and separated from the scrotal swelling by a well-defined constriction, was a hard slightly elastic mass about the size of a hen's egg. This was very sensitive to pressure. The patient was etherized, and taxis was tried without success. An incision was then made over the upper inguinal swelling. The sac was opened and found to contain a little knuckle of intestine close to the ring, with a mass of omentum behind and below it. This omentum was connected by a narrow band with a larger mass below in the scrotum. The constriction of the sac between these two parts was so narrow that it had to be incised before the hernial contents of the scrotum could be drawn out and passed on into the abdominal cavity.

This constriction may have represented the neck of the original sac, and when the second protrusion took place it pushed the whole of the old hernia before it and formed a new sac for itself.

Van Buren gives a different explanation.⁸ After describing a similar condition, he says:

"The constriction at the middle of the sac, which formed so prominent a feature in this case, giving it the shape of an hour-glass, seemed to me to mark the point where nature had attempted, unsuccessfully, to obliterate the communication between the tunica vaginalis proper and the tubular prolongation connecting it with the peritoneal cavity. . . . I suspect from frequent examination of the parts in the dead body, that the process of peritonum connecting its cavity with the tunica vaginalis testis remains unobliterated more frequently than is generally supposed, and that the effort at obliteration is more marked at the *internal ring* and just above the testis, and that this circumstance explains the frequency of stricture at the internal ring, as well as the constriction observed at or below the middle of the sac."

The next three cases I propose to consider together, as they all illustrate and emphasize what I believe should be a rule of practice, and which I would state as follows: When, after the reduction of a hernia either by taxis or by herniotomy, the symptoms of strangulation or of great peritoneal irritation continue. When the patient is not soon relieved of the vomiting, pain, and tympanites, a further exploration should be made; the wound should be re-opened, and if a sufficient explanation of the symptoms is not found there, the incision should be continued upward, the abdomen should be opened, and a search should be made for the condition which is causing the trouble.

INTERNAL STRANGULATION FOLLOWING THE REDUCTION OF AN OLD INGUINAL HERNIA.

Fanny R., aged forty-eight, had long had an inguinal hernia of the left side, which gave but little trouble, being easily reduced. On January 12, 1885, the hernia came down about the size of a goose's egg, and as it did not go back readily, Dr. H. E. Marion, of Brighton, was summoned, and easily reduced it. The patient, who was of intemperate habits, was drunk at the time he saw her.

She continued to have pain in the abdomen, and two days later began to vomit. The bowels remained constipated. Dr. Marion saw her again, and on January 17th he succeeded in getting her to enter the hospital. She was at this time very feeble. The abdomen was now considerably distended and tympanitic.

The old hernial sac was empty, and was drawn in towards the ring.

With the concurrence of Dr. John H. Mans, it was decided to do laparotomy. The abdomen was opened in the median line below the umbilicus. Immediately, a number of coils of sloughing, black intestine were brought to view. About three feet of small intestine was thus gangrenous. A search was made down along the sloughing bowel for a twist or a band that would account for the strangulation. On account of the softened condition of the gangrenous coils, the greatest gentleness was observed in the manipulations, and the distended condition of the rest of the intestines made this search very difficult.

At last, what was thought to be a soft band around a portion of the intestines was found and separated with the fingers. The gangrenous portion was then drawn out as far as possible on the front of the abdomen and secured to the skin; it was then opened.

This operation, which was done as quickly as possible, on account of the collapsed condition of the patient, was not followed by any relief, and death ensued twelve hours later.

No thorough autopsy was allowed, but I opened up the abdominal wound, and after puncturing and collapsing a number of coils of intestine, I was able to follow the gangrenous portion down to where it was constricted by a narrow, firm band, which stretched from the bottom of the old hernial sac across to the mesentery of a neighboring intestine. This band was evidently an old adhesion which had once formed between the mesentery and the sac, and which had gradually become stretched and thickened into a firm fibrous band.

The course of events in the production of the strangulation which caused death was as follows:

The intestine came down on one side of this band and entered the old hernial sac. When reduced, it went up into the abdomen on the other side of the band. This left a small coil of intestine looped down beneath this band. The peristalsis of the bowel gradually pulled more and more through, until so much had passed through this opening as to fill it up and cause a constriction which led to the death of all of the intestine beyond.

FEMORAL HERNIA, HERNIOTOMY; INTESTINE DISPLACED FROM AN EXTERNAL SAC INTO AN INTERNAL ONE, IN WHICH IT REMAINED STRANGULATED.

Charles R. D., aged sixty-seven, had had a right femoral hernia for a number of years. It usually went back at night. On the night of December 9, 1885, it did not go up, and on the following day he had great abdominal pain, with nausea and vomiting. The patient dosed himself liberally with cathartics without result, and finally, towards evening, he sent for his physician, Dr. C. V. Bemis, who, finding taxis unavailing, sent him to the hospital.

I saw him at ten o'clock that evening. The hernial tumor was about the size of an orange, and situated over the femoral ring. The patient was feeble, with a weak pulse. Ether was given, and after a short attempt with taxis, herniotomy was done. The sac was opened, and found to contain a dark, plum-colored knuckle of intestine, another bit of bowel not discolored, and a piece of omentum.

The neck of the sac was incised, but still the hernia

⁸ Contribution to Practical Surgery, 1865.

did not go back. With the finger inside of the peritoneum, another more extensive incision was made, and then the hernial contents were returned with some difficulty. Deep stitches were taken in the neck of the sac, and superficial ones in the skin.

December 11th. The patient had comparative comfort for the rest of the night, but in the morning had considerable pain at the umbilicus. The temperature was below 99° F., and the pulse between 80 and 90.

December 12th. Still some pain, easily controlled by morphia. Vomited once or twice. Temperature 98° F. in the morning, 99° F. in the evening, pulse 90.

December 13th. Severe attack of pain in the early morning relieved by one-fifth grain of morphia. At the time of my visit, in the middle of the day, the pulse, which had risen from 90 on the previous day to 120, was almost imperceptible, and he died at two o'clock.

At the autopsy, made by Professor Fitz, a loop of intestine was found in a gangrenous condition close down to the inside of the femoral ring. It was contained in a sac composed of peritoneum.

The accompanying illustrations after Bryant, show in diagram the various ways in which a strangulation may occur in this region after the apparent reduction of a hernia.

FIG. 1.

FIG. 2.

FIG. 3.

No. 1 represents the condition when a hernia is reduced "*en masse*" or "*en bloc*"; that is, when the whole sac, with the strangulation unrelieved, is pushed back into the abdomen. This was not the condition in our case, for the bowel was distinctly put back out of the sac.

Either of the other two illustrations may represent the condition that we had.

No. 2 shows a herniated loop of intestine pushed back out of the external pouch, but still strangulated in the neck of the sac.

A consideration of the case of hour-glass contraction of the sac reported above will give an idea of how this condition of things might be brought about; for if the hernial contents were displaced from the lower sac into the upper one, and if this upper division of the sac were at the time within the abdominal wall, how easily the condition might be overlooked and left uncorrected.

The third figure represents a sac with a diverticulum just within the abdominal wall, into which the hernial contents might find their way, when reduced, out of the external sac. To which of these last two conditions our case corresponded, it is impossible to say.

This case is, further, a good example of the deceptive character of the symptoms in intestinal strangulation. On the first two days after operation, we had no more disturbance than might result from a mod-

erate peritonitis about the herniated loop of intestine, so that although the question of internal strangulation was considered in view of the persistent constipation, still it was not deemed wise to interfere by operation. When the symptoms of danger did come, the fatal issue followed so closely upon them that no opportunity for interference was given.

GANGRENE OF HERNIAL SAC AFTER HERNIOTOMY; LAPAROTOMY; RECOVERY.

Pera S., a small, thin woman, giving her age as forty-five, but looking much older, entered the Massachusetts General Hospital, October 26, 1887. The history was, briefly, that a lump had been noticed in the right groin for three years. Since first seen it had never disappeared. Three days before entrance she began to have great pain in the abdomen, especially in the right iliac region, and the bowels ceased to move. For one day she had been vomiting.

The tumor was about the size of a hen's egg, and was tender to the touch. It lay above Poupart's ligament. She was etherized, and, after an ineffectual attempt at reduction by taxis, herniotomy was done.

The sac contained no fluid. The protrusion consisted of a small knuckle of intestine and a little bunch of omentum, and had come out through the inguinal ring. The constriction was incised, and the hernial contents were returned to the abdominal cavity. The sac was turned in, and the pillars of the ring were stitched in front of it.

October 27th (the next day). The patient was very uncomfortable, and was still vomiting. There was diffused tenderness over the whole abdomen, but the pain principally complained of was in the right iliac region. She had, in the morning, a small involuntary defecation, and another slight one after a turpentine enema. Towards evening, she was failing rapidly. She was still vomiting, and the pulse, which had been rapid from the first, became very weak and intermittent. Another enema was given without effect.

It being evident that some serious condition still existed in the neighborhood of the hernia, and there being some hope that it might be remedied by an operation, laparotomy was advised, and was accepted by the friends.

Ether was given and the wound was reopened, and was then prolonged by an incision parallel to and just outside of the linea semilunaris, opening the peritoneal cavity. The intestines were gently pushed away from the neighborhood of the inguinal ring. They were perfectly free, no part of them being engaged in any ring or sac, and no portion that was seen being discolored, as it recently strangulated.

Upon investigating the hernial sac, which had been turned back into the abdominal cavity, it was found somewhat discolored, and had the appearance of commencing gangrene. It was, therefore, drawn down out of the abdomen, and the peritoneum was closed behind it.

October 28th (the following day). The patient was free from the intense pain from which she had previously suffered, and said that she felt much better. She was able to bear a small amount of liquid food.

She continued to hold her own through the next two days, and on October 31st she had several small, loose discharges from the bowels.

November 1st. The bowels again acted freely.

November 3d. The sloughs from the old sac came

away. From this time there was slow, but steady improvement, and the wound finally closed.

November 19th. She was taken home by her friends. Some weeks later she was heard from, and had then resumed her household work.

In this case, the dangerous symptoms were evidently due to the commencing peritonitis about the sloughing hernial sac, and the improvement following the laparotomy, by which the gaugreous portion was brought outside of the peritoncum, was immediate. I have not been able to find another instance of just this condition of things. Perhaps it is sometimes an unsuspected cause of death after hernia.

Besides the cases of immediate trouble following herniotomy or reduction by taxis, we have at times conditions leading to obstruction of the bowels a considerable time after the reduction of the hernia.

A case of umbilical hernia operated on by me, and reported some years since, illustrated this condition of things:

The patient, a woman of forty-seven, bore the operation well, her bowels acted naturally in due time, and the wound healed by first intention. On the ninth day she took a little solid food for the first time, and this change from a liquid diet was followed by considerable pain in the abdomen, referred to the neighborhood of the umbilicus, and colicky in character. A little hardness and fullness was to be felt just to the right of and above the umbilical region, and this part was tender to pressure. The bowels being somewhat constipated, several small doses of castor oil were given, with the effect of producing a free, easy defecation, and of relieving the pain.

Several times during her subsequent stay in the Hospital the same course of events was noticed; namely, that when her bowels were constipated she suffered from cramps, with occasional vomiting, and that these symptoms were relieved by a mild cathartic.

It was believed at this time that the bowels were somewhat obstructed, probably owing to adhesions

about the loop of intestine that had been returned while inflamed, and had set up a local peritonitis in its neighborhood.

Treves,⁴ in an interesting article on the "Forms of Intestinal Obstruction that may Follow after Hernia," enumerates the following conditions that may give rise to intestinal obstruction some time after the reduction of a hernia, either by taxis or by herniotomy:

(1) Organic stricture of the bowel, as a result of hernia.

(2) The herniated loop, after reduction, becomes fixed to the abdominal parietes by adhesions.

(3) The two ends of the herniated loop may be fixed together by adhesions.

(4) The adhesions between the reduced loop and the parietes may develop into a band, behind which, subsequently, strangulation may occur.

(5) To the inflamed peritoncum about the hernial orifice a part of the omentum may become adherent, and lead to subsequent internal strangulation.

The case I have just narrated probably is to be placed in the second or third of these classes, for the first symptoms followed so soon upon the operation that a stricture or a band would have hardly had time to form.

The prompt relief that always followed laxatives deterred us from operative interference at that time, and led us to hope that in time the condition might correct itself.

The patient, when she left the Hospital, was especially warned of the danger, and I asked her to let me know at once if she ever had an attack of abdominal pain which did not yield to laxatives. It was, therefore, a great disappointment to hear later that she died of just such an attack, which her attending physician treated with opiates, and without laxatives.

The table which follows gives the main facts of all of the cases of strangulated hernia operated upon by the writer. It is added as a contribution to statistics upon the subject.

No.	Name	Age	Residence	Variety	Strangulated for	Operation	Result	Remarks
1	James H.	38	Everett	Inguinal	6 hours	Herniotomy	Recov.
2	Alfred B.	32	Boston	Inguinal	2 days	Taxis	Recov.
3	John J. R.	50	Boston	Inguinal	7 hours	Taxis	Recov.
4	Mary C.	47	E. Medford	Umbilical	3 days	Herniotomy	Recov.
5	Fanny R.	48	Brighton	Internal	5 days	Laparotomy	Died.	Three feet of sloughing intestine.
6	50?	Charlestown	Inguinal	Taxis	Recov.	Success after $\frac{1}{2}$ hour of taxis.
7	James P.	23	Chelsea	Inguinal	12 hours	Taxis	Recov.
8	Ava D.	33	Boston	Femoral	2 days	Herniotomy	Died.	No autopsy.
9	O. P.	..	Boston	Inguinal	Taxis	Recov.
10	John L.	40	E. Cambridge	Inguinal	Incarcerated	Herniotomy	Recov.	Hydrocele of Sac.
11	Harry L.	15	Boston	Inguinal	4 hours	Taxis	Recov.
12	Natick	Inguinal	1 day	Herniotomy	Recov.
13	Charles R. D.	67	Medford	Femoral	1 day	Herniotomy	Died.	Internal strangulation.
14	William J. M.	36	E. Boston	Inguinal	5 hours	Herniotomy	Recov.
15	Isidore M.	29	New York	Inguinal	2 days	Herniotomy	Recov.	Hour-glass sac.
16	Kate L.	34	Cambridge	Femoral	12 hours	Herniotomy	Recov.	Second operation.
17	Pera L.	45	Boston	Inguinal	3 days	Herniotomy and Laparotomy	Recov.	Sloughing sac.

STRANGULATED INGUINAL HERNIA. HERNIOTOMY. CONTENTS OF SAC FOUND TO BE CANCEROUS. RELIEF OF SYMPTOMS.¹

BY S. J. MIXTER, M.D.

Mr. Y., a patient of Dr. Norton, of Walpole, a farmer, fifty-five years of age, had had an inguinal hernia for a great many years and was able to keep it in place by means of a truss, and, when it did come down, could easily reduce it himself.

Forty-eight hours before I saw him his hernia came down suddenly while he was lifting. He could not reduce it, and after keeping quiet for twenty-four hours, sent for a physician. Attempts at reduction, both without and with ether, proving unavailing, the foot of the bed was raised and ice bags placed on the hernia. I saw him the next day. He was then suffering severe pain in the tumor; there was considerable pain and tenderness of the abdomen with some distension. There had been no movement of the bowels since the descent of the hernia, and there was constant nausea and occasional slight vomiting. The right scrotum and inguinal regions were red, swollen and tender. The patient was etherized and attempts at reduction being unsuccessful, it was decided to perform herniotomy. The symptoms were not particularly urgent, but had been growing steadily worse for twenty-four hours, under the best conditions for their relief.

The tumor was not resonant in any part. On opening the sac no fluid escaped, and a mass was found filling it which resembled neither omentum nor bowel, but which seemed more like a much-thickened sac, within the first. It was entirely irreducible and somewhat congested. On cutting into this mass a small cavity was opened and a small amount of jelly escaped. On introducing the finger more jelly and a large number of small grape-like masses were found to fill this and adjacent cavities. The tumor being adherent, was separated as far as the much enlarged ring, but after enlarging the ring and passing the finger round the neck of the tumor, it could not be reduced and was ligatured and removed as high as possible, the removed mass resembling in size and shape a large pear. The finger passed through the ring could feel a large mass passing backwards and upwards into the abdominal cavity and apparently firmly fixed. Symptoms of strangulation were entirely removed by the operation and the patient did well for about ten days, only a slight amount of pus escaping along the drainage-tube tract, when distention of the abdomen and a high temperature appeared and the patient died. The probable cause of death was peritonitis, perhaps caused by sloughing of the pedicle of the tumor left in the ring, its structure being such that a necrosis might easily take place in the mass.

The tumor was examined microscopically by Dr. W. F. Whitney, who pronounced it colloid cancer.

— M. Pasteur's recent proposition to extirpate the rabbits which infest New South Wales by the introduction of the chicken-cholera microbe, is strongly opposed by a government official who asserts that the proposition involves greater danger than the pest it seeks to remove.

THE REIMPLANTATION OF A TREPHINE BUTTON OF BONE.¹

BY HERBERT L. BURELL, M.D.,
Surgeon to the Curney and Children's Hospitals.

It would seem that the credit of introducing the important step of replacing a trephine button of bone in the skull belongs to William MacEwen,² and its full significance has perhaps not been fully appreciated, for it is possible to replace bone that has been completely divided from all its attachments, especially from its periosteal covering which has always been considered to be so important for its life and growth and to feel assured that it will live, places upon a definite practical, working basis bone-grafting which may well become one of the great possibilities of surgery.

MacEwen in 1885, stated that he had reimplanted the fragments of divided trephine buttons, in eleven cases, only twice did the replacement fail, and in these two cases the majority of the fragment lived.

The able paper of MacEwen upon "Osteogenic Factors in the Development and Growth of Bone,"³ which has recently appeared, is evidently the result of mature thought upon the subject of bone-growth, and accepting for the time MacEwen's experiments and many of his conclusions, we are lead to conclude that the periosteum is no longer the principal seat of bone-growth but to deem it simply an investing membrane which supplies a comparatively small amount of nutriment to the bone. The medulla is also shown to have but little to do with the growth of bone, in fact, the osteoblastic cells are believed by MacEwen to be capable of reproducing themselves. These statements at first are somewhat startling but we are beginning to receive accounts of successful efforts at bone-grafting, and this specimen which I have been fortunate enough to secure, has seemed to me of enough importance to place upon record. The trephining was an exploratory one done on a boy aged thirteen, to determine the presence or the absence of a depressed inner tablet of the skull that might have accounted for a group of existing cerebral symptoms. Operation: the child was etherized and the localization lines were drawn by Dr. W. N. Bullard; a large semilunar incision was made with the base downward, including the cicatrix; a second incision was made through the periosteum, and this was completely and freely elevated from the bone, which was then removed with a large trephine; no fracture was detected, and no abnormal appearance of the dura mater was found; an exploratory puncture with a trocar was made into the cerebral substance in the direction of the median portion of the ascending frontal convolution, entering perhaps four inches—no result. The bone which had been carefully preserved in an antiseptic solution was then carefully replaced in the skull, the periosteal flap was secured in position by a fine continuous catgut suture, and the overlying structure were similarly dealt with. Drainage being secured in the scalp by a dozen or more strands of catgut; an antiseptic dressing was applied and the recovery from a surgical standpoint was uneventful. When the dressing was first removed at the end of two weeks, the wound was found completely united; for a short time after this a dressing was kept on the boy's head as a protection against any injury to the recently

repaired structures. The child's cerebral symptoms gradually grew worse, and he finally died in the Boston Lunatic Hospital, in December, at the expiration of nearly eight months after the trephining, and for the specimen I am indebted to Dr. W. N. Bullard. (See cuts.) The trephine button has completely

I. Outer Surface.

II. Inner Surface.

united by bony union throughout its circumference, and is perfectly firm in its position; it rests in a plane a little below that which it formerly occupied, and is a little whiter than the surrounding bone structure; there has been raised from the external surface of the bone the overlying periosteum (Cut I.) in order that the condition of the reimplanted button might be observed.

The important lesson which this specimen seems to teach, is that hereafter one should regard the removal of a trephine button in the same light as an exploratory incision through the abdominal walls, since in each case it opens up a very important field for exploration, which can be again closed by reuniting the abdominal walls or by replacing the trephine button.

— A Chicago congressman has lately introduced a bill in the House of Representatives which provides for a penalty to be inflicted on persons bringing infectious diseases into the United States, authorizes the supervising Surgeon-General of the Marine Hospital Service to build a laboratory, and repeals the act creating the National Board of Health. The bill is put forward, it is said, in order the more easily to kill the bill establishing a Bureau of Public Health.

— A Liverpool daily paper contained (January 27th) the following advertisement: "Wanted at the end of February, a nurse able to bottle a baby."

A CASE OF NECROSIS OF THE TEMPORAL BONE; REMOVAL OF THE LABYRINTH; RECOVERY.¹

BY FREDERICK L. JACK, M.D.,
Assistant Surgeon to the Massachusetts Charitable Eye and Ear Infirmary; Aural Surgeon to the Lowell Hospital.

The patient was first seen by me at the Children's Hospital in consultation with Dr. H. W. Cushing, who gave the following history:

Willie B., eight years of age, was brought by his mother to the hospital on August 24th for the relief of pain in the left ear. An examination showed the following condition: The left meatus filled with a purulent and offensive discharge. A polypoid mass springing from the posterior upper portion of the canal close to the outer orifice, prevented an inspection of the condition of the middle ear. There was paralysis of the muscles of the face on the left side. The region of the mastoid was red, swollen, and there were distinct signs of fluctuation.

The patient was etherized and a free incision made down to the bone, evacuating a quantity of pus. A small piece of dead bone was discovered about on a level with the superior wall of the external meatus, which was readily removed, and the probe found to pass into the mastoid an inch. The polypus was snared off. The wound of incision was dressed and the patient kept in bed. The head symptoms were partially relieved for a few days by the operation, but the otorrhea continued, accompanied now with free discharge from the wound behind the auricle.

September 1st. The case was referred for treatment to the Massachusetts Charitable Eye and Ear Infirmary. The polypus which had reappeared was removed, revealing the condition of the middle ear. The membrana tympani was found entirely destroyed, and the tympanic cavity filled with granulations. The malleus and incus were absent. Probing discovered no necrosis either in the middle ear or in the post-aural sinus to the depth of an inch. The ear and wound were frequently syringed with solutions of permanganate of potash and boric acid. While syringing into the sinus, water freely passed into the meatus from the inferior wall of the tympanic cavity. Under treatment all symptoms diminished, and at the end of ten days the mother was requested to bring the boy as an out-patient. She neglected to attend till October 20th. In the meantime the post-aural swelling had alternately subsided and reappeared. The pain in the ear and mastoid for a few nights was intense. Under ether, the wound previously made behind the ear, which had partially closed, was enlarged, and dead bone readily felt with the probe at the depth of an inch and a half. The sequestrum resisted gentle attempts for its removal, and considering the relation of the bone to the cranial cavity, and the liability of dangerous hemorrhage, it was decided not to use force, but to allow it to separate by natural processes. The patient remained in the Infirmary for a week, and during the time suffered very little pain, an anodyne being required but once.

The case now passed from observation until November 17th. At this time the auricle was standing far out from the head, and the swelling over the mastoid had extended farther down the neck. The purulent process was active, and the ear and wound freely discharged.

¹ Read at the meeting of the Surgical Section of the Suffolk District Medical Society, Feb. 1 1888.

Under ether the sequestrum was felt with the probe about an inch from the opening of the wound. It was somewhat movable, and after several attempts was extracted without much difficulty with forceps, and proved to be the greater part of the osseous labyrinth.

When last seen on January 9, 1888, the opening over the mastoid had nearly closed; the discharge from the ear very much diminished in quantity; there was improvement in the facial paralysis, and the patient was in good health. The deafness was profound on the left side, all tests of hearing giving negative results.

The writer has briefly reported the case, believing it of interest in the following respects; namely, the excision of so large a portion of the labyrinth, its removal through an opening in the mastoid process, and the progress of the case toward a favorable termination.

REPORT ON PROGRESS IN SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

SUBLIMATE SOLUTION AS A DISINFECTANT, AND ITS VALUE IN SURGICAL DRESSINGS.

LAPLACE¹ found that sublimate dressings, as ordinarily used, are free from germs, but that they sometimes contain bacteria, and hence fail to accomplish their purpose, for the antiseptic action of such a dressing is questionable. Also, that the antiseptic power of sublimate was much impaired when it came in contact with a substance containing so much albumen as blood. To overcome this, hydrochloric acid was added, and though the result was satisfactory, this combination was not found practical. Tartaric acid was then substituted,² and given a practical trial in Bergmann's clinic and polyclinic, from which experience, Laplace concludes:

(1) That the tartaric acid sublimate solution is a perfect one for the disinfection of wounds. For fresh wounds, simple washing or irrigation is required. Infected wounds require to be daily irrigated for ten to twenty minutes with this solution. A permanent dressing of tartaric acid sublimate gauze is used.

(2) This dressing can be combined with iodoform to advantage where the usual indications for iodoform exist.

(3) Laboratory experiments and practical use of this solution and gauze give better results than the usual dressings.

(4) Wounds are not irritated by it.

(5) The acid solution dissolves the sublimate more readily than water. The solution does not injure the bandages as some acid solutions do.

(6) Such dressings are thoroughly free from germs—aseptic.

¹ Deutsche Med. Wchnschr., 1887, xiii, 40.

² Sublimate solution:

R. Sublimate	1.00 grammes.
A.c. tartarici	5.00 "
Aq. distill.	1000.00 "
Gauze or cotton is prepared with:	
R. Sublimate	5.00 grammes.
A.c. tartarici	20.00 "
Aq. distill.	1000.00 "

Absorbent cotton or gauze is soaked about two hours, wrung out, and dried.

DISINFECTION OF HANDS.

The following are the conclusions of Fürbringer, one of the most recent investigators of this subject:³ That the "subungual space is the most difficult part to clean. The most essential thing of all is the preparation of the skin and nail, since the disinfecting power of sublimate and carbolic solutions does not depend on the strength of the liquid alone. As the result of many experiments, Fürbringer recommends the following method, which is said to give almost ideal results:

- (1) Clean the nails mechanically of all visible dirt.
- (2) Scrub the hands, nails especially, with brush, warm water, and soap.
- (3) Immerse hands for one minute in alcohol (not weaker than 80%), and while wet plunge into a sublimate (2%) or carbolic (3%) solution, where they should remain one minute. Fürbringer prefers the sublimate solution. This method is now in use in Professor Bergmann's clinic in Berlin.

MAJOR OPERATIONS FOR DIABETIC GANGRENE.

Professor König reports two cases,⁴ the results of which may cause a revolution in the present method of treatment of these distressing cases. In this class of patients there is a marked predisposition to inflammation and local necrosis which has deterred surgeons from operating on such patients. These processes are the result as usual of germ invasion, but more exaggerated, since the conditions are more than ordinarily favorable for their development, and the tissues become necrotic more readily. French surgeons with Roser state that this necrosis can occur in not only advanced cases in old patients, but also in middle-aged ones, where the general condition of the patient and the absence of thirst or polyuria have prevented recognition of the real trouble. The course recommended by König is that in all cases of spontaneous or even post-traumatic phlemonous and gangrenous processes the urine should be examined carefully for sugar, and since the presence of sugar and albumen may be transitory,⁵ these examinations should be repeated.

CASE I. König saved a gouty old man, aged seventy, with gangrene of the fifth toe, which had extended to the ankle. The amount of sugar had increased from 2% to 4% and there was anorexia, emaciation, coma, etc. König rapidly amputated the leg at the middle. The urine on the following day showed no sugar. The wound remained aseptic. The patient was discharged at the end of eight weeks. No sugar. The latter, however, reappeared later.

CASE II. A well-nourished brewer, aged forty, who had had phlebitis of the left leg two years previously, and for the preceding nine months emaciation and thirst, gradually developed gangrene of the left hallux and phlegmon of the foot. Continuous hicough, low fever, albumen trace, sugar 4%; sugar diminished to 2½% by careful general and local treatment; amputation. In four days no sugar, and other symptoms absent. Discharged well in six weeks. No sugar six months later.

In both cases extensive arterio-sclerosis and calcification of numerous small arteries were found. König recommends the following rules for treatment in these cases:

Antidiabetic and antiseptic local treatment. If no

³ Untersuchungen und Vorschriften über Disinfection der Hände des Arztes u. s. w. Wiesbaden, 1888.

⁴ Centr. f. chir., 1887, s. 225.

⁵ Redard, 1886.

improvement and further delay involves danger to the patient, a radical operation (generally an amputation) in the most aseptic manner possible.

THE PRACTICAL VALUE OF SECONDARY SUTURE FOR CLOSURE OF WOUNDS.

This practice, already used by Kocher,⁶ and Neuberg,⁷ and recently described by Bramann, of Berlin,⁸ has again been brought to notice by Helfferich,⁹ who regards it as a most valuable resort in certain classes of wounds. The following conditions are those in which this method can be used:

(1) After operations in tissues which are the seat of septic inflammation, such as amputations, excisions, abscesses, phlegmon, bursal inflammation, etc., when immediate closure of the wound is unsafe. In a few days, when the wound-surface is clean and there is no fever, the wound can be advantageously closed. Some care must be used since the sutures cut out easily. In normal tissues a dry absorbent antiseptic dressing is best during this period, but under other circumstances a moist one must be used.

(2) In cases of bone or joint tuberculosis by an iodoform tampon the specific action of the iodoform (P. Brun) is utilized. Also, since local tuberculous processes are destroyed by cicatricial contraction, the slight amount occurring in the two to six days intervening before the closure of the wound is also used to advantage. This is not suitable in knee resections, however, since granulation growth prevents accurate apposition of the ends of the bones.

(3) In recent wounds, when, on account of cavities, hæmorrhage is difficult to control; for example, extirpation of the kidney or thyroid, severe head injuries, brain operations, etc.; also for amputation in time of war, or where, for any reasons, primary union is imperilled.

(4) For operations on or about the anus, genito-urinary tract, mouth, or naso-pharynx. An anæsthetic is usually required. Buried sutures are used as in fresh wounds. Inverted wound-edges are to be carefully raised so that the wound can be accurately closed. In amputations the skin-flaps must be cut larger than when the wound is to be closed at the operation to allow for the contraction which occurs.

IMPROVEMENT OF CICATRICES.

Lassar¹⁰ claims to have prevented—by continually removing the exuberant granulations of ulcerating surfaces, so that the surrounding skin may have opportunity and time to extend in over the granulating surface—the white radiating scars often seen after such lesions. This treatment delays the rapidity of healing. The writer especially mentions cases of lupus canceroid and acne rosacea hypertrophica. His results, as shown in his article, are surely quite attractive. For further details of the method the reader is referred to the author's original article.

HEAD INJURIES.

Ginger¹¹ has investigated the cases of such injuries on record at Czerny's clinic from 1877 to 1881 inclusive. He has classified them as follows:

- (1) 90 cases, injuries of soft parts.
- (2) 23 " compound fracture of the skull.
- (3) 12 " fracture of the base.
- (4) 8 " no osseous lesion, followed by brain symptoms.

CLASS I. Forty-eight showed no brain symptoms. In ten cases such symptoms were of slight importance and short duration. In two cases (brothers) hæmatophila delayed recovery. In six cases erysipelas, with one death (case forty-one). The sooner treatment is commenced and the less a wound is exposed the more favorable the prognosis. Hæmatophila delays healing and cicatricial contraction, subsequently in some cases causes marked neuralgia.

CLASS II. All due to direct violence to vault of skull. They recur in order of frequency as follows: vertex, frontal, temporal and occipital regions. Symptoms of brain abscess can occur subsequent to several years following the injury. Late nervous and physical symptoms can also occur which may incapacitate the patient for work. The results of this class show twenty-three (nine cases trephined) recoveries, nine (five cases trephined) deaths, four of which were hopelessly injured. In all five cases of operation the latter had no influence as contributing to the fatal result. Compound fractures of the vault are to be considered grave in proportion to the degree and duration of the accompanying brain symptoms. In regard to ability to work, with certain reservations the prognosis depends on whether the motor tracts of the cortex are involved or not, and to what extent.

CLASS III. Twelve cases, three deaths. Prognosis influenced by the presence and duration of brain symptoms. Most common lesions are disturbances of sight and hearing. Prognosis favorable where the tympanum, and not the labyrinth, is affected, or where no suppuration occurs; where due to exudation, which will be absorbed, and not to tearing or crushing of the optic nerve or Sehpsphäre (visual centre).

Here, also, as in Class II, is the possibility of late development of brain abscess, or of nervous and physical symptoms. The worst prognosis is where extensive comminuted fractures co-exist with fractures of the vault.

CLASS IV. Eight cases. Where apparently an exudation capable of absorption or capillary apoplexy, with slight lesions of brain substance, exist, without any osseous lesion which can be discovered. Here the prognosis is generally favorable, but should be a guarded one. The history in detail of the cases referred to by the writer accompany his monograph, and are of great interest and value.

CLOSURE OF THE JAWS AND ITS TREATMENT.

In a paper by J. Ewing Mears,¹² he summarizes all of the previously suggested methods, and then gives his own method of treatment in six cases, with results. It is as follows: An external cicatrix is avoided by excision of the upper portion of the ramus, the coronoid, and the condyloid processes through the mouth. A straight, sharp-pointed bistoury is introduced beneath the masseter muscle on a level with the last molar tooth of the lower jaw. An Adam's saw is introduced through this opening, and the ramus is sawn through. The periosteum, with the overlying tissues, including the muscle, is raised by an elevator, and the wound thus enlarged. Then the tissues on

the inner surface are separated by the elevator, and the bone twisted outward forcibly by lion-jawed forceps. If it breaks at the neck of the condyle, the process is afterwards chiselled out. Hemorrhage may be controlled by packing the wound-cavity with sponges. The wound-cavity is then packed with iodoform gauze, renewed every third day.

The formation of a new joint is aided by the use of a mouth-gag, beginning at the end of a week, and continued at varying intervals for from six to eight weeks. Chewing-gum materially assists in the maintenance of a false articulation.

LIGATION OF THE LINGUAL ARTERIES FOR CONGENITAL MACROGLOSSUS.

In advanced cases of macroglossus, some operation for reducing the size of the tongue is usually required, whether by a wedge-shaped excision of its tip, or by an attempt to obtain contraction by multiple punctures with a thermo-cantery (Helfferich method). In the primary stage of the affection, shortly after birth, such operative procedures are dangerous to so young a patient, and the various methods to check its development, such as scarification, with or without subsequent use of astringents, parenchymatous injections, compression by bandaging, section of the genio glossus muscles, have not been satisfactory. The affection is a lymphangiomatous, and its microscopic structure shows a strong resemblance to certain forms of elephantiasis.¹¹ Fehleisen, after witnessing a satisfactory result in a case of elephantiasis cruris from ligation of the femoral artery, determined to try the same treatment in a case of congenital macroglossus, since the two affections showed a similar pathological process, and in August, 1886, carried out this idea at the Royal Surgical Klinik in Berlin, by ligating both lingual arteries in a child aged thirteen months.¹² The tongue, which, before the operation, projected one centimeter beyond the margin of the lips, contracted in twenty-four hours to almost its normal size. In two days, a dark-blue color was the only abnormal condition noticeable. This also disappeared in about a week. One year after the operation, no tendency to recurrence had been noticed. The advantage claimed for this procedure is that the danger of the usual operation to infants is avoided, and that the result is more satisfactory.

THE TECHNIQUE OF LATERAL PHARYNGOTOMY FOR THE REMOVAL OF TUMORS OF THE TONSIL.

Obalinski,¹³ of Krakau, has reviewed this subject with reference to an improved operation. He finds the following methods on record:

(1) Langenbeck: incision from angle of mouth obliquely downward and backward to the level of the thyroid cartilage, and subsequent section of lower jaw by sawing.

(2) Lugenbeck — modified: above incision shorter above, but continued below to the level of the cricoid cartilage.

(3) Gussenbauer: incision from anterior border of sterno-cleido-mastoid insertion to mastoid process, to upper tracheal rings.

(4) Kocher: "an angular incision, a combination

of two and three, which gives an excellent opening to the pharynx, and sawing the lower jaw at the anterior border of the masseter.

(5) Mikulicz-Gussenbauer incision, with addition of section of lower jaw at posterior border of masseter muscle, and enucleation of same, which allows a better entrance to upper part of pharynx; mouth not opened at all, and only at last, thereby avoiding necessity to tracheotomy.

Obalinski considers that the first four methods are suitable only for tumors situated in the lower part of the pharynx, and that 5 is most favorable for extirpation of tumors of the tonsil. Its disadvantage is the subsequent ankylosis following enucleation of the jaw. He proposes a modification which he has used successfully for removal of a large tonsillar sarcoma extending from the palatine arch to the right ary-epiglottic fold, tracheotomy, slight hemorrhage; tube removed on sixth day; patient fed ten days with oesophageal tube; recovery in five weeks, with perfect function of lower jaw. Obalinski first removed the affected cervical glands through the Gussenbauer incision, ligated the lingual and facial arteries, and divided the stylo-hyoid and digastric muscles. A second incision was then made perpendicular to the first, and extending to the angle of the lower jaw, which was sawn through at this point. By pulling outward the divided ends the tumor was fully exposed and dissected out. The operation was completed by uniting the jaw with two silver wires, and closing the soft parts with silk sutures. The "G." incision was closed after introducing a rubber tube packed around with 20% iodoform gauze into the oesophagus. This method, Obalinski claims, avoids the disadvantage of the Mikulicz method. This method can be used for operations on the third branch of the fifth nerve.

HEMORRHAGE AFTER TONSILLOTOMY.

A number of cases are on record where alarming hemorrhage has occurred after this operation, and which has been considered by Chassaignac as having its origin from its proximity to the internal carotid artery. This has been contradicted by Lihhart (1849), who claims that the tonsil is not, as is commonly believed, separated from the carotid only by the pharynx wall, but that the posterior part of the "pharyngo-maxillary" space; that is, between the lateral wall of the pharynx, the internal pterygoid muscle, and the uppermost cervical vertebrae, contains the great vessels. He also claims that the vessel is not drawn out with the tonsil when that is pulled forward from its niche between the fascial pillars, but that the distance between the gland and the artery is increased by so doing. Luschka also confirms this. Other textbooks differ. To decide this point, Zuckerkandl¹⁴ has carefully investigated this point, and concludes that "Linhart's space" is not a definite one, but that a muscle layer, besides the pharynx wall and fat, separate the tonsil from the artery; that it is out of the question that the internal carotid can be injured by tonsillotomy or probe-pointed bistoury. The same is true of scarification of the tonsil or incision of tonsillar abscesses, unless where, as by a quick motion of the patient's head, the knife penetrates deeply towards the vertebrae. In incising a retro-pharyngeal abscess, such an accident is possible where the vessel is sur-

¹⁶ Schmidt's Jahrbücher, 1887, No. 9, 369.

rounded by pus. Zuckerkandl explains these severe hemorrhages after tonsillectomy by the fact that the fibrous capsule of the tonsil prevents the divided vessels from contracting. This is avoided by not making the cut in the plane of the lateral wall of the gland, best done by simply cutting off top of the tonsillar swelling. Hemorrhage from this source is best controlled by ligation *in situ*, or, if impossible, by prolonged pressure with the Pean-Mikulicz forceps. Ligation of the carotid is unnecessary.

INTRA-CAPSULAR EXTIRPATION (PARTIAL) OF THYROID WITHOUT TAMPOON OR HEMORRHAGE.

Hahn,¹⁹ reported at the Sixteenth Surgical Congress at Berlin, a new method for removing portions of an enlarged thyroid gland. The preliminary steps consisted in ligating both superior thyroid and thyroidea ima arteries, exposing the gland freely by dissection, and clamping both inferior thyroid arteries with forceps, the spring of which is just strong enough to compress the vessel without injuring the recurrent laryngeal nerve, should it happen to be included. The capsula propria of the left lobe is then incised, and with knife, or scissors and forceps, the desired amount of gland structure is removed without injuring the capsule, except at the above-mentioned point. The right lobe is then treated in a similar manner. In this manner, masses of gland can be "shelled out," as myomata from a uterus, without hemorrhage. Hemorrhage from capsular vessels is controlled by ligation. The wound is packed with iodoform gauze. The forceps are removed from the inferior thyroid arteries at the end of twenty-four hours, secondary suture at the end of a few days. Almost complete union at the end of ten days. In this way, one avoids tearing or crushing the thyroid, operates unimpeded by hemorrhage, avoids injury to the recurrent laryngeal nerve, and diminishes the danger of sepsis, since there is neither arterial ligation *en masse*, nor necrosis from crushing or tearing of gland tissue. Hahn claims that this method compares favorably with the "partial resection and ligation *en masse*" of Mikulicz, the "ligation of the thyroidea arteries" of Wöller, the "shelling out and tamponade" of Wolf, or the intra-capsular method of Socin and Garre, or unilobular extirpation.

CANCER OF THE LARYNX.

The following data relating to this affection are of value and interest.²⁰ Although papilloma are the most frequent form of laryngeal tumor, malignant growths are not so rare as has been supposed, and of the latter, carcinoma is the most frequent. Primary cancer occurs most frequently in males, and between the ages of fifty to sixty. Hereditary influence is unproved, and the exciting causes uncertain, although it is claimed that cold, damp climates, inhalation of irritating gases, abuse of alcohol and tobacco, especially combined with violent use of the voice, seem to have an influence on its development. That repeated attempts to remove benign growths instrumentally is at present an open question. Its most frequent origin is the ventricular bands and vocal chords; that is, the middle and superior part of the larynx, generally on the left side. Of 167 cases, 149 were epithelioma, and 18 eucephaloid in character. Prognosis fatal.

Duration shows wide limits. Twenty-seven cases of v. Ziennsen are thus classified: Nine (33%) died within one year; fifteen (55%) died between one and six years; three (11%) died after six years; one was alive fifteen years after disease discovered.

Its average duration is variously stated, some claiming that the disease rarely lasts longer than eighteen months, others²¹ that twenty-three months for epithelioma, and three years for the eucephaloid form. Treatment is, as a rule, palliative. Laryngotomy and laryngectomy are the two alternatives which the surgeon can offer his patient. The former prolongs life,²² relieves dyspnoea, adds much to the comfort of the patient by giving rest to the larynx, and is, in fact, the most useful procedure, although a palliative one.

Laryngectomy gives about 30% recoveries²³ of all cases, benign, as well as malignant.²⁴ Its high mortality, however, makes this procedure one of considerable danger. Partial laryngectomy:²⁵ if the patient survives the operation, there is a good prospect of future immunity from recurrence; where the disease is circumscribed, it is a much less fatal operation, but its ultimate results are not yet definitely known. Hence the true statement of operative treatment is that tracheotomy or laryngectomy leaves the patient with no immediate danger of death, without voice or hope of recovery, and a possible prolongation of life of, at least, one year, and possibly two or three; while laryngectomy, with a more than even chance of an immediate fatal result, gives the patient, if he survives the operation, a good prospect of complete immunity from recurrence, but with an artificial voice and a constant dread of recurrence, either local or metastatic. Hahn²⁶ advises as early an operation as possible in carcinomatous growths, where the cells show a great tendency to assume a horny character; but in the infiltrating forms, which show a great tendency to necrosis and ulceration, while, perhaps, the surrounding soft parts are already involved, a simple tracheotomy, when increasing dyspnoea renders this necessary, is wiser treatment than to attempt a radical operation.

STATISTICS ON MAMMARY CARCINOMA.

Dr. Hans Schmidt²⁷ gives the following data, obtained from a careful review of the records of these cases at Küster's Klinik from May, 1871, to the end of 1885, showing how far the radical operation for extirpation of carcinoma from the breast and axilla is successful as regards a permanent cure: Total number of cases, 228, including two male patients. Six cases unoperable. Glandular swelling was present in 97%, absent in 3%. In 71.77% was glandular affection recognized before the operation. In 26.25% glandular involvement was demonstrated only at time of operation. These last figures show how important the removal of axillary glands is in these cases. Total mortality, 10.81%, which has gradually diminished until seq.: 1883 = 12%; 1884 = 4%; 1885

¹⁹ Fauvel.

²⁰ Fauvel. Epithelioma: average prolongation of life, twenty-five months. Eucephaloid form: average prolongation of life, nine months. Ziennsen: average prolongation of life, three to forty-two months.

²¹ Park, R. Reference Handbook of Med. Sciences, Ann. of Surg., 1886.

²² Hahn: 72 cases; 7 partial operations, 13 permanently cured to time of report, 25 deaths within two weeks after the operation. Sabonin: 87 cases; 49 (56.1%) recoveries, and the best results as regards prolongation of life.

= 2.5%; 1886 = 0%. When three years is taken as the limit for permanent recovery, such a result was obtained in 21.5%. This, however, would be increased to 26.4% if a period of two years without recurrence denotes a permanent recovery.

In a majority of cases the disease recurred locally in the skin, operation cicatrix, muscles, sternum, ribs, pleura, remaining mamma, metastasis of other organs, and finally, carcinomatous infiltration of the infra- and supra-clavicular and cervical glands. Schmidt concludes that the axilla should be dissected out in every case, whether glands are felt or not before operating; that this method will give better permanent results; that the danger from the operation is not increased. In doubtful cases of mammary tumors, small sections of the growth removed through an exploratory incision should be submitted to a microscopic examination, and, if found to be carcinoma, that a complete operation is indicated. Benign tumors not involving a greater part of the breast cannot only, as a rule, be diagnosed, but also be dissected out without removing the unaffected gland tissue. The preservation of the subscapular nerves is quite important for the preservation of the function of the arm. The arm should not be fixed longer than twenty-four hours.

PULMONARY SURGERY.

Considerable activity exists in this new branch of surgery, and various reports of cases are appearing here and there, which are, perhaps, worthy of a little attention on the part of surgeons. Godlee²⁵ has summarized the subject, and submits the following conclusions: (1) Gangrenous cavities should always be sought, and, if possible, opened, and the prognosis, if the operative procedure be successful, is not bad. (2) The same may be said in regard to abscesses caused by the rupture of purulent collections from other parts into the lung, at least, as regards the pulmonary complication. (3) Abscesses connected with foreign bodies must be opened, and if the body be not found it must be remembered, if of any considerable size, it probably lies near the middle line. If recognized, these cases should be treated early by a tracheotomy incision. (4) Bronchiectatic cavities, when single (a very rare condition), will be cured by operation; when multiple, they offer but slight chance of relief by our present surgical methods. Still, for the reasons stated, an attempt may be made to open the main one, if such is to be found, but only if the pleura has been ascertained to be adherent. (5) Tubercular cavities should only be opened in cases where the cough is harassing and the cavity single. Injections may be used to relieve symptoms, but cannot be expected to be curative.

G. Foubert²⁶ has collected the various published cases, to the number of eighty pneumotomies: forty-seven recoveries. Twenty-nine of these successful cases were operations for hydatids, a comparatively simple and safe operation. His summary is as follows: Tuberculous cavities, in which there was incision made either with or without a resection of the rib, seven cases. In one case the patient is said to have recovered; in another, the patient is said to have lived some time. In the remainder the patients died. Abscess of the lung, fourteen cases, with nine cures and five deaths. In two of the fatal cases death could not

be attributed to the operation. Gangrene of the lung, eighteen cases, with nine cures, two ameliorations, and seven deaths. Bronchiectasis, twelve cases, with four cures.

A NEW SURGICAL OPERATION FOR THE TREATMENT OF CANCER OF THE STOMACH.

There has been, practically, three operations performed for carcinoma of the stomach, namely: (1) pylorotomy; (2) gastro-enterostomy; (3) Loretta's dilation of the pylorus after gastrotomy. A. C. Bernay,²⁷ discusses these operations, and concludes that any operation aiming at a radical extirpation of the disease in all cases is intrinsically absurd, not because the disease is essentially incurable, but because, in the majority of cases that seek assistance at our hands, the disease has ceased to be a local one, and a radical extirpation is entirely out of the question. The most plausible operation which has been suggested is Wölfler's gastro-enterostomy, but this operation has met with but little favor, because few are willing to undertake a surgical feat of this magnitude in a case which they know to be doomed at all events.

Bernay calls attention to an important point, that cancer of the stomach originally grows inside the muscular layer, towards the lumen of the organ, and acting on this, he proposes (and records two cases) to perform a gastrotomy, and then removes the cancerous growths from within the stomach by means of curettes or other suitable instruments. For a detailed description of his two cases, one is referred to the original article, and certainly the results make the method worthy of consideration.

Bernay concludes that "in cases of carcinoma the aim of the operation is very high; it is intended only to give a short prolongation of life, free from the tortures of obstruction." He considers that his operation exactly fulfills the foregoing indications, and believes that the percentage of mortality will be a very small one. He considers the operation indicated in all cases of pyloric cancer with stenosis, in which the radical extirpation is impossible on account of adhesions to neighboring organs, or infiltration of the lymphatic glands.

A METHOD OF IDENTIFYING THE ORIGIN OF THE JEJUNUM.

Halm²⁸ speaks highly of the following method of finding the first loop of the jejunum in operations for gastro-enterostomy. The omentum and transverse colon are drawn up through the abdominal incision, and the operator with the index-finger and thumb of the right hand locates that portion of the pancreas resting on the vertebrae. A loop of intestine crosses from right to left just below the pancreas. If this does not yield under traction, it is certain that the loop is the origin of the jejunum.

Maydl's²⁹ experience in his second case of jejunostomy seems to indicate that this method is not, however, an absolutely sure one.

EXTRA-PERITONEAL EXPLORATION.

Prof. W. Snegureff, at the Second Congress of Russian Physicians,³⁰ called attention to this method of abdominal exploration. Later, Bardenhauer³¹ wrote an

article which has been the most detailed description yet printed. Its advantages are, that it is less dangerous than a laparotomy, and that many tumors or abscesses being extra-peritoneal, are thus more easily reached, and it is well-known that the peritoneum can be separated over a large area with impunity, as has been often proved by ligation of the iliac artery, supra-pubic cystotomy, or nephrectomy. The regions which Bardenhauer considers accessible by this method, are: (1) The renal (for retro-peritoneal tumors, exploration of the liver, head of pancreas, duodenum, colon, cæcum and spleen); (2) the hypogastric, a transverse cut above the symphysis (for exploration of the bladder, for example, calculi or tumors, or uterus, extra-uterine foetation); (3) the thoracic, namely, separation of the peritoneum from the diaphragm through an incision along the sub-costal arch. Sniegureff recommends also lateral incisions. The recent notice taken of Bardenhauer's publication by Wölfler⁵⁵ and by Gubarroff⁵⁶ who claims that the outer surface of the pancreas, pylorus, duodenum, kidney, ureters, a large portion of the surface of the liver, gall-bladder and most of the pelvic organs can be explored through the linea alba or an incision about three cm. right or left from it, is proof that this method has a certain value. For diagnostic purposes this may be true, but where an extensive exploration and probable operation is to be performed, a direct incision into the peritoneal cavity, affords the most rapid and thorough method since the eye as well as the finger explores the field. It also seems quite possible that an accidental tear could often open the peritoneum contrary to the intention of the surgeon, in which case no advantage would be gained and much time lost.

(To be continued.)

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

MEETING, Wednesday, February 1, 1888, the chairman, DR. J. COLLINS WARREN, presiding.
DR. F. L. JACK reported a

CASE OF NECROSIS OF THE TEMPORAL BONE; REMOVAL OF THE LABYRINTH; RECOVERY.¹

after which he made the following remarks:

The case is an uncommon one. Up to 1875, sixteen similar cases had been recorded. On looking over the transactions of the American Otological Society, since that date, I found records of two cases in which the greater part of the labyrinth was removed. In 1879 there was a case at the Infirmary under Dr. Blake, an old man, in whom a portion of the cochlea was removed, and subsequently a part of the semi-circular canals.

DR. C. J. BLAKE: An interesting point in relation to the exfoliation of so large a sequestrum from the petrous bone is well illustrated by this case, and by the three plates taken from the admirable photographic atlas of the ear of Drs. Randall and Morse,

which are here exhibited, and that is the manner in which the cochlea and semi-circular canals can separate from the surrounding bone in these cases of necrosis. An examination of the plate exhibiting a section of the bony labyrinth in a child shows that the labyrinth stands by itself, and is distinct from the surrounding petrous bone, from which it is separated by diploetic tissue, a mechanical condition which permits easy separation and the pushing of the labyrinth, or of portions of it, outward by the growth of granulation tissue in the diploetic space. As is shown in the third plate, this diploetic line of demarcation still exists in a greater or less degree in the adult, and the case last mentioned by Dr. Jack in a man seventy-two years of age, is an interesting evidence of this process of separation and extrusion, which makes possible the removal by natural means of a large portion of the labyrinth without extension of the inflammatory process to the adjacent meninges.

DR. H. L. MORSE: I have only one word to say, and that is that I never saw so large a portion of the cochlea and semi-circular canals removed at one time as in this case of Dr. Jack's, and it is an exceedingly valuable case, both to hear reported, and also to have the drawings and the photographs from. It is very rare to have so large a portion exfoliated. In regard to a case which Dr. Jack spoke of, the specimen from which is on the table, I would like to say a word or two on the subject of the exfoliation of the cochlea. This case was one which came into the Eye and Ear Infirmary. It was a little girl five years old. She came in for persistent polypi, which were removed several times while she was there, and which grew again very rapidly. That was all that seemed unfavorable in regard to the case. She was pretty well nourished and a fairly healthy child. She disappeared from the Infirmary, and was lost sight of for some months. Afterwards I saw her, by the kindness of Dr. Cabot, at the Children's Hospital, and she then had facial paralysis, and was totally deaf on that side. She was a good deal emaciated, and was a very sick child, with mastoid swelling, and swelling in front of the meatus on the cheek. The sequestra, one of which is the cochlea, and another one a portion of one of the semi-circular canals, and a third a part of the facial canal in section, were removed without ether and without much pain.

She improved and left the Children's Hospital, and last summer, which was a year or so afterward, I was treating her brother, and one day she came with her brother, and I had a chance to examine her again. At that time the discharge had entirely ceased for months, and she had a cul-de-sac at the inner end of the external auditory canal, from which there was no discharge, there were granulations, and it was not tender on probing. She still had the facial paralysis complete, and still was totally deaf on that side. The history covers about two and a half years, if my memory serves me, and shows how, in a child, where the bone is not very solid, it is possible for the greater portion of the inner ear to be thrown off without killing the patient, as one would expect it to do in a place so near the brain.

DR. E. D. SPEAR: I have very little to add to what has been so admirably spoken in regard to the exfoliation of the bony labyrinth, but would like to call the attention of the Section to what we ought to think of, the prophylaxis of such cases. The special-

¹ See page 314 of the Journal.

⁵⁵ Centbl. f. Chir. 1887. Bd. XIV, p. 627.

⁵⁶ Ibid. p. 865.

ist is called upon at the last minute, perhaps, to remove the result of neglected ear disease, though it seldom falls to the lot of one to be so fortunate as to remove the bony labyrinth and get recovery. The importance of attending to a purulent ear is not appreciated at the present time even in this community. We, as specialists, know this, but the general practitioner, perhaps from his position, is not so apt to know this fact. I would like to speak of a case that I am conversant with. I can vouch for it, for my authority is a good one, though I will not name him. There was a patient treated in a neighboring city for some weeks for so-called malaria. The disease, of whatever character it may have been, went on, and the patient was found by her grandmother in her coffin. The old lady, in her inquisitiveness, approached her grandchild, and casually noticed a piece of cotton projecting from her right ear. She removed it, and a stream of pus spurted out and besmeared the inside of the casket. The moral is obvious, I think.

DR. GANNETT showed a microscopic specimen of
BACILLI OF TUBERCULOSIS IN THE URINE,

and said: I suppose almost every surgeon in his experience has cases in which he suspects the possibility of tuberculosis involving some part of the urinary tract. The diagnosis at the present time can often be made quite certain by finding in the urine tubercle bacilli; and I have here a specimen from such a case,—a case of Dr. Porter's in which he suspected tuberculosis, and a specimen of urine was sent to me for examination. The specimen, prepared in the usual way, shows very beautifully the bacilli, and so renders the diagnosis quite certain. In this case there was disease of both testes, and also of the bladder. What is to be seen here is just in the middle of the field, the red, short, narrow rods, which show in marked contrast to the blue cells in the neighborhood. They lie quite free, and are the tubercle bacilli. The specimen is prepared in the same way in which sputa is prepared, by allowing the sediment to settle, then taking a drop and mounting it on the cover-glass, and that is then stained in fuchsin, and afterward in the contrasting stain of blue.

DR. MIXER: Of course it is necessary to have some open ulceration in the urinary tract in order to get the bacilli?

DR. GANNETT: Yes, I think it is. I examined three cases of tuberculosis of the epididymis without finding bacilli.

DR. MIXER: I have known cases of tuberculosis of the kidney where examination had failed to show the bacilli, and the autopsy showed the presence of tuberculosis.

DR. GANNETT: There is one thing which is quite manifest—all observers have noticed it—in regard to the appearance of the bacilli in these cases. In the sputa the bacilli are scattered—they are seen at various points. But the general experience has been that in connection with the urine the bacilli are present in the arrangement that you get in pure cultures of the bacilli. They have the form something like that you see there, and sometimes a little more pronouncedly S-shaped. So far as this specimen goes, there are three glasses, and there are in the three but two of these little colonies, and no free bacilli at all. I think it is quite possible that they have sometimes

been overlooked, owing to the fact that they are in colonies, and are few and far between, and may not have been made out.

DR. J. C. WARREN showed a specimen which illustrated the result of an operation of

WIRING THE FRAGMENTS FOR UNUNITED FRACTURE
OF THE FEMUR.

The wire was twisted and left buried in the bone, after which the superficial parts healed over the wound. The specimen showed the bone with the suture *in situ* two years after the operation. Dr. Warren said that he understood there was no sinus in the soft parts, and that he thought the specimen interesting in that it showed what becomes of a wire suture buried in bone.

In connection with the question of burying the wire suture in the bone, DR. CABOT briefly reported the following case:

Last July a heavy man entered his wards in the Massachusetts General Hospital with a compound fracture of the patella. He had fallen from a high beer wagon into a street paved with cobble stones. Under ether the opening was enlarged and the patella found smashed into a number of pieces. The greater part of it was removed piecemeal and the parts attached to the quadriceps tendon above and to the ligamentum patellæ below, were brought together and secured with two silver wires, the ends of which were turned down on the bone. Drainage-tubes were introduced into the dependent parts of the joint and an antiseptic dressing was applied. Healing took place by first intention, and two months later the man had a movable and useful knee.

On Christmas day, less than six months after the injury, this patient came to my office with a simple fracture of the same patella. He had for about a month had a habit of running up stairs two steps at a time, and on the previous evening he had run down stairs two steps at a time to show what he could do. Missing his footing he fell and broke the patella anew. The separation had occurred about on the line of the union of the former fragment. He was sent again to the hospital where he was under Dr. Porter's care, and the case was treated on a splint like an ordinary simple fracture of the patella and he made a good recovery without accident. The wires never seemed to cause the least disturbance.

This shows how little reaction metal sutures may set up.

DR. CABOT then read some notes on the

COMPLICATIONS MET WITH IN HERNIOTOMY,²
and DR. MIXER reported a

CASE OF STRANGULATED INGUINAL HERNIA; HERNIOTOMY; CONTENTS OF SAC FOUND TO BE CANCEROUS; RELIEF OF SYMPTOMS.³

DR. ELLIOT said: I am sure it is a great point to realize the fact that the abdomen should be reopened if the trouble persists. I made up my mind, two years ago, that after any abdominal operation that did not do well I should reopen the abdomen, and I have never regretted that, and I have seen very good results. The curious thing is that in the literature of reopened abdomens, after ovariectomies especially, there have been several cases recorded where nothing has been

² See page 329 of the Journal.

³ See page 313 of the Journal.

found, no serous pathological change, and yet recovery has taken place when it seemed, before the operation, as if death were almost inevitable.

Dr. J. C. WARREN: I remember to have seen, in consultation with Dr. W. J. Otis, a case of reduction *en masse*. When I first saw the hernia it had been reduced by taxis, but the symptoms persisted. I opened the coverings of the sac, and found a good, open ring. There was a neck, and just inside that neck was a strangulated loop of intestine, which could be felt. Introducing the finger into the first ring, a second one could be felt behind it. That was divided, and the intestine replaced. The patient died very shortly afterwards, but he died with a reduced intestine. I made the diagnosis of a reduction *en masse* with an inner sac and an hour-glass contraction. The intestine went out of one compartment into another.

Another interesting point in connection with herniotomy is the condition of the intestine. What shall we do in a case of very bad-looking intestine? A case bearing on that point occurred to me a year or two ago: A lady was suddenly seized with a strangulated hernia, which was very acute, and in about thirty hours from the first symptoms I operated. The intestine was very black indeed, but careful inspection of it showed that it was entire. It had a shining surface. I decided to replace it, but put a tube in, so that the wound was not closed entirely. The patient did remarkably well, and had several movements from the bowels during the latter part of the first week, and I congratulated myself that I had replaced the intestine. About the tenth day, fecal discharge began in the sinus where the drainage-tube had been. There were very copious discharges. The lady's father was a physician, and was very much disturbed, and wanted to know what the prospects were. I concluded that it would probably heal spontaneously, and it did heal in about three months from the time of the original operation. It closed spontaneously, and the patient has had no trouble from stricture since. A slight hernia existed six months or a year later, which necessitated the use of a truss. I have not heard from the patient since that time. Many of these fecal fistulae do close spontaneously. They are not exactly the same thing as an artificial anus, because the mucous membrane of the bowel is not in contact with the skin, but communicates with the skin by a little fistulous opening, which is of a cicatricial character, which may become stricture, like any other canal of that kind, and thus close the opening. Such a canal may be the remains of an abscess which has burst and discharged fecal contents. These cases heal more readily than those of artificial anus, which do not tend to heal.

The question of resection of the intestine comes up here, and it seems to me, although I have had little or no experience in that operation, that the indications are not met so well by a resection and suture of the intestine as by bringing it out and suturing in the way that Dr. Cabot did, the great point being to relieve the obstruction; that is more completely relieved by an artificial anus, than by restoring the continuity of the canal, which may not let out all the gas, owing to pressure, kinking of the bowel, adhesions to the wound, etc. And then we all know how much easier it is to suture a bowel secondarily, when there are no complications present except those of a fecal fistula.

Dr. H. L. BURRELL then showed a

SPECIMEN OF THE REIMPLANTATION OF A TREPHINE-BUTTON OF BONE.⁴

Dr. CABOT: I received a note from the secretary, asking me to bring a trephine-button, which perhaps may be of interest to look at, by the side of this specimen of Dr. Burrell's, as illustrating what sometimes is found in trephining for epileptic or other brain symptoms. The child had had a blow on the head, I think two years before, had suffered from convulsions for the intervening two years very constantly, and during the year before the operation the convulsions were as many as twenty-four or twenty-five a day. There was nothing to feel at the seat of fracture except two cicatrices in the skin. A crucial incision was made through the cicatrices. On coming down to the bone a very minute crack was found in the outer table, and the bone including that was taken out. We were fortunate in striking a prominence on the inside, pretty nearly on the plumb centre. Running from this prominence down toward the base was a line of depressed bone, and that was cut out with a cutting forceps. Everything went perfectly well surgically, and the wound healed by first intention. The child was isolated during the healing. During the three weeks of isolation there were no convulsions. The patient was then brought down into the ward, because some contagious cases came in. That night she had seven or eight convulsions, and since that time they have been very nearly what they were before the operation. After the changes in the brain had already taken place they could not be removed. I will say that in that case the child had been seen the year before the operation, and an operation was advised at that time, and then the mental capacity was very good. In that year of waiting the patient changed from a very bright child to almost a drivelling idiot.

Dr. WARREN: I would like to ask if this operation of replacing the button has ever been done before.

Dr. BURRELL: So far as I know, MacEwen is the originator of the procedure. The literature of the subject is necessarily very small, because it is comparatively a recent thing.

With the exception of an allusion made by Dr. Senn in a series of letters written to the *American Journal of the Medical Sciences*, which appeared last summer, the only definite statement is in 1885, by MacEwen, where he reports his eleven cases. He takes a button and subdivides it and reimplants it, in order that he may have drainage. I do not know that an autopsy of any of his cases has been obtained.

Dr. GANNETT: I made the autopsy in Dr. Burrell's case, and was very much struck by the entire absence of evidence of any reactive inflammation either in the dura or in the brain below. There was a small circle which corresponded with the circle of bone, but with that exception there was no thickening whatever in dura; showing that there had been no reactive inflammation there, and consequently it must have been a very antiseptic operation.

Dr. NEWELL: I would like to ask Dr. Burrell what he put the bone into after it was removed.

Dr. BURRELL: It was placed in a warm sublimate solution of 1-1000, and kept there until it was replaced.

⁴ See page 313 of the Journal.

NEW YORK NEUROLOGICAL SOCIETY.

MEETING held Tuesday, March 6, 1888, the President, DR. C. L. DANA in the chair.

DR. DANA presented the report of a case of

THOMSEN'S DISEASE,

with specimen of muscle, in some respects an atypical case. The patient was a male, thirty-five years of age, single. He had been delicate as a child, and at fifteen or sixteen years had masturbated, but not to excess. At fourteen years he had developed talipes varus in the left leg, but tenotomy had been performed with cure. The symptoms of the disease in question had not appeared until the twentieth year, when the patient had commenced to notice stiffness of the hands and difficulty in opening the hands when closed; also stiffness of the leg and of the muscles of mastication. The patient tired easily, especially in the arms. Until recently he had had a high-pitched child's voice and a child's larynx. Erections were incomplete and there was mental difficulty in concentrating his thoughts. The muscle development was good. Measurement around the biceps gave ten inches in both arms. The dynamometer showed forty degrees in the right hand and thirty-eight in the left, the normal measurements by the reader's dynamometer being forty-five to fifty. There were tonic contractions of the calf muscles and of the pillars of the fauces. Striking the muscles of the arm or forearm caused tonic contractions in these muscles. Striking the biceps with the percussion hammer would cause a welt and a myoid tumor as well. There was no increase of irritability to mechanical stimulation in the nerves. By galvanism Erb's reaction was obtained. There was increased muscular irritability and a closure tonic contraction which persisted as long as the current continued to be passed. There was closure tetanus both to the cathode and the anode. There was no opening contraction to either pole. A peculiarity of the reaction to faradism was that in the arm the contractions persisted after the current ceased to be passed. There was no ankle clonus, no increase of the reflexes and no spastic condition. In the eye the fundus was normal, but there was a fibrillary contraction of the muscles of the lid. There was vasomotor weakness, the hands and feet were red and easily became cold.

A piece of the supinator longus had been removed, and for comparison, a piece of the same muscle from the reader's own arm. These specimens had been placed in weak alcohol, and stained with picro-carmin and bismark brown. The specimen taken from the patient showed increase of the nuclei of the sarcolemma, an increased number of fibres, and in addition, a dichotomous division of the fibres such as was found in the muscle of the heart. This was characteristic of Thomsen's disease, and was supposed to indicate reversion to an earlier type. The tonic contractions of this disease, too, were characteristic of unstripped muscle fibre.

DR. GEO. W. JACOBI had examined the specimens and compared them with the specimens from his own case. He did not consider this the typical case which Erb's monograph had described. Erb had excluded all of the published cases but eight. Erb's typical case showed no disease of the central nervous system. In Dr. Dana's case there was at least a suspicion of

such disease. The reactions of the muscles, too, were incomplete, or failed to comply with the requirements as given by Erb. The speaker did not, however, believe in Erb's lines. He thought they were too close. While this case did not come under the heading as limited by Erb, it did come under the name as understood by others. Erb's theory was that of a disorder of the muscles themselves, a congenital malformation of the muscular system. If the fissuring of the muscles and the increase of nuclei in the case under discussion were dependent upon a central affection, this alone was an interesting fact. It would demonstrate that microscopically alone, a diagnosis of myotonia congenita could not be made. Our knowledge of primary muscle affection was not yet on a solid basis. It was possible that there was first trouble in the central nervous system, from which the other proceeds.

DR. HEITZMAN had examined the specimens with a low power and had been impressed with the belief that this was not a genuine case of Thomsen's disease. In the typical case the nuclei of the muscles were augmented. The reader of the paper had made Erb's mistake when he spoke of the nuclei of the sarcolemma. The sarcolemma was a structureless membrane. There was also augmentation of the sarcoplasm or muscle corpuscles. There was too much muscle substance from the earliest period. Hence the name, myotonia congenita. Dr. Dana's case, on the contrary, could not be called congenital, as the disease had not developed until the twentieth year. Second, the muscle fibres were not distinctly augmented in size. If compared with those in Dr. Jacobi's case, the difference was marked. Third, the fissuring was not prominent. For these three reasons he was loth to accept the diagnosis. He was, on the other hand, unable to tell what else the condition could be.

DR. EMERSON had examined the eyes. There was no insufficiency of the muscles and the pupils had reacted all right.

DR. STARR realized that we could not yet lay down any positive deductions in regard to electrical reactions. In degeneration we got the pure reaction of degeneration, an intermediate reaction of degeneration, and the normal muscle reaction. Erb had given the reactions for three cases only. Other cases might not substantiate their results. He considered Dr. Dana's case valuable, and one to be put on record. For reliable data a large number of cases were required. Even Dr. Heitzman's objection of muscular anomalies was not fatal to the theory of its being a case of Thomsen's disease.

DR. DANA explained that he had not called the case one of myotonia congenita, but an atypical case of Thomsen's disease. It remained to be proved whether myotonia was always congenital. He had recently seen a case which commenced at the eighth or tenth year. Since Erb's book, four additional cases had been reported besides his. He agreed with Dr. Heitzman that the enlargement of the fibres was not positive. He had with a stage micrometer measured the fibres in the specimen from Dr. Jacobi's case, in that from the case under discussion, and in that from his own arm. He had found the fibres in the first, $\frac{3}{16}$ to $\frac{1}{16}$ of an inch broad; in the second, $\frac{2}{16}$ to $\frac{1}{16}$, and in his own $\frac{1}{16}$ inch. Thus, in the case under discussion, some of the fibres were larger and some smaller than the normal. The increase of the nuclei, however, was in some of the specimens shown

typically as in Erb's plate. He acknowledged that the fissuring might have been produced artificially by tearing. Electrically there was greatly increased irritability of the muscles both to galvanism and faradism. The contractions were tonic with closure tetanus. There was normal excitability of the nerves. Clinically, the patient presented the phenomena of Thomsen's disease. It remained to be proved whether the phenomena of Thomsen's disease could be produced by disorders in which the central nervous system was involved.

DR. STARR presented a specimen of

TUMOR OF THE BRAIN.

The patient was a woman, at the time of death, fifty-six years of age, who for two years had presented the general symptoms of tumor of the brain: vertigo, projectile vomiting, dulness of the mental faculties, and optic neuritis. During the last five months she had been carefully examined, but without obtaining any evidence which would locate the tumor, if one occasion were excepted, when, during an attack of vertigo, she fell forward and to the right. This was not a permanent symptom, and was the only evidence pointing to cerebellar disease. The tumor was of the size of a hen's egg. It was found on the under surface of the tentorium, simply resting upon and compressing one lobe of the cerebellum. There were no adhesions, and it was unfortunate that no symptoms had pointed to its location, as it might have been easily removed. In 1878, Nothnagel had remarked that tumors of the lateral lobes of the cerebellum did not give rise to the symptoms of incoordination common to other cerebellar tumors.

DR. J. WEST ROOSEVELT presented the report of a case of

BASEDOW'S DISEASE, WITH AUTOPSY.

The case was one of negative interest. The patient had been admitted to the wards of the Roosevelt Hospital, May 25, 1887. The patient was a female, widowed, forty-seven years of age, a housekeeper. Both the personal and family history was good. Two years before admission the patient had commenced to complain of palpitation, dyspnoea upon exertion, and swelling of the throat, which was largest upon the right side. The patient could not lie upon the right side. In the course of a year the eyes commenced to protrude, and at the time of entering the Hospital she had a profuse watery diarrhoea.

The pupils were found to be equal, the reaction to light and accommodation good. The lids did not follow the eyeballs. The neck measured thirteen inches around the lower thyroid region, and ten and one-half inches around the upper thyroid region. There was dysphagia to solid food. The pulse was 100 to 120, and the respiration 38. The apex-beat was found in the fifth space, mammary line. There was epigastric pulsation, and the area of dulness was slightly increased. There was a short systolic murmur at the apex. There was a systolic thrill over the jugulars, and a continuous venous hum. The pulmonary resonance was exaggerated. The veins of the retina pulsated, the arteries did not. There was no tremor. The patient lived until May 31st. She suffered from a watery diarrhoea and restlessness, but was not otherwise sick. In walking to the bath-room one evening, she fell dead on the floor. Autopsy

showed the thyroid reduced in size, but still moderately enlarged and of a pink color. The kidneys showed a trace of fibrous tissue, but otherwise the organs were normal. There was apparently nothing abnormal in the medulla nor in the sympathetic or vagus nerves. Microscopic examination of these parts also showed nothing.

DR. W. O. MOORE had seen twelve cases, all females, average age forty years, the youngest thirty-one, and the oldest forty-five years. Ophthalmic examination had showed simply enlargement and tortuosity of the bloodvessels. Great relaxation of the bowels had been present in one of the cases, having as many as ten evacuations in the day, which it was impossible to control. Electricity had been of no avail in these cases. All had presented the three characteristic symptoms—exophthalmos, thyroid enlargement, and rapid heart action. All had the symptom to which Von Graefe first called attention; namely, a disturbance of the usual coördination of the movements of the eyeball and the upper lid, so that when the patient looks downward below the horizontal meridian the lid no longer follows the eyeball in its motion, but halts in its course. This fault in the action of the lid was supposed to be due to some defect in the orbicularis, and was not present in cases having prominent eyes from other causes. Occasionally, the prominence was so great as to cause the eye to be exposed at all times, both when waking and asleep. In one case in his experience suppurative had occurred, and the eye had been lost.

The patient, a female, aged forty-five years, stated, when a child, she had lost the sight of the right eye through an accident; that one year before coming under observation she had noticed commencing enlargement of the neck, dyspnoea upon exertion, and prominence of the left eye. Six months later vision for near objects commenced to fail, and four weeks before coming under notice the left eye had become painful and inflamed. Examination, December 13, 1886, showed in the right eye phthisis of the bulb, total corneal leucoma, and exophthalmos so marked that although the eyeball was atrophied, the lids were as full as in the usual healthy state. The eyelids on this side covered the globe fully when shut. In the left eye, the exophthalmos was so great that the lids were retracted to their full extent, and the eyeball was dislocated through the commissure of the lids. The ocular conjunctiva was chemotic, and the cornea was cloudy through its whole extent. At the upper border of the cornea was a serpiginous ulcer. In other words, there was present a keratitis from loss of nutrition and exposure to the air. The pulse was irregular at 110. The patient was admitted to the Post-Graduate Hospital, the outer canthus was cut, hot water applications were made, and the parts were protected by lanolin. In spite of treatment perforation took place, with escape of the vitreous and lens. The eye began to recede, and phthisis bulbi developed.

Had this case been seen earlier, the writer would have united the upper and lower lids, thus covering the eyeball. At the end of a few weeks the lids would have been reopened, when, as a rule, the exophthalmos would be found improved and the corneal trouble removed. For constitutional treatment, the patient should receive digitalis, ergot, and tonics. This case was remarkable from the fact that an eye was lost by suppurative, and that this loss was asso-

ciated with phthisis in the other eye. The loss of an eye from exposure was so rare that the writer knew of but ten reported cases in this country, while Wells reports only one case.

Dr. STARR had been interested in the report of Dr. Roosevelt's case. The fact that no lesion had been found in the sympathetic in this case did not, of course, prove anything conclusive. Ross had reported eight cases in which such lesion had been found out of twelve cases as far back as 1882. The pathology, however, was not clear. It was difficult to understand how any one lesion could produce all of the phenomena of this disease. The hypothesis accepted by Gowers was that of lesion of the vagus nucleus in the medulla. The rapid pulse would be accounted for by the loss of the inhibitory power of the vagus. It was known, too, that vaso-motor disturbances were produced by irritation of the medulla in this region. The speaker had, some time ago, collected twenty-one cases of lesion of the medulla, in eight of which the lesion was in its upper part, in the region of the nucleus of the tenth nerve. In all of these cases there were subjective flushings and objective increase of perspiration; while in the thirteen in which the lesion was in the lower part of the medulla there were no vaso-motor symptoms whatever, thus substantiating the hypothesis of the physiologists, that there is a vaso-motor centre in the medulla, and that this centre is in the neighborhood of the nucleus of the tenth nerve.

The speaker had personally observed seven cases, five in the female and two in the male. In all but one, palpitation of the heart had been the first symptom. This disproved the theory that the goitre was primary, and that the other symptoms were due to the pressure of the tumor upon the pneumogastric nerve. The pulse had ranged between 90 and 155. In all but one the eyes had been prominent. In six there had been nerve symptoms, in four tremors, in four Von Græfe's symptom, in six flushes. Mental disturbance had been present in one case in which there had been delirium every night for several months, and subacute mania for several weeks. The first symptom in this case had been insomnia, which resisted treatment. The reader supposed it to have had its origin in a condition of the vessels of the brain similar to that in the back of the eye and the thyroid gland. Digitalis had done no good in his experience. Ergot and bromide had quieted the tremor, but no drug which he had tried had reduced the heart. He had used electricity according to Benedict's recommendation, but without result. He had himself, when in Vienna, watched the treatment of three cases in which Benedict had given a good prognosis, but had failed to find any reduction of the pulse while the galvanism was being used. In his own cases he had tried every method described as galvanization of the sympathetic. He had placed the poles upon either side in front of the sterno-cleido-mastoid, behind the sterno-cleido-mastoid, and at the back of the neck and epigastrium, carrying the current as high as nine milliamperes, which was as strong as could be borne with a small electrode, and he had never been able to obtain any retardation of the pulse. Dr. Janeway expressed himself as having had the same experience.

Dr. ROCKWELL had met about thirty cases of this disease, and in nine cases he had obtained an approximate cure. He had employed diet, galvanism, and

very full doses of digitalis, bromide of zinc, ergot and iron. He had authentic records of his results. He believed that the cases not benefited by treatment were organic, and that those benefited were functional in origin. Those having all of the cardinal symptoms were more often responsive to treatment than those in which the symptoms were more incomplete. He recalled a case in which there was a pulse of 110 reduced to 80. There was puffiness of the eye-lid in this case. In the galvanic application one pole had been placed over the eye-lid and the other behind the sterno-cleido-mastoid muscle at its upper third. In another case presenting the three symptoms for several years the pulse had ranged from 130 to 150. There was dilatation of both pupils, and a pulsating swelling over the solar plexus. This patient was placed upon a milk diet and persistently treated for many months when the pulse had fallen to below 100 and the swelling of the thyroid and the exophthalmos had become less.

Dr. STARR asked whether Dr. Rockwell had obtained reduction of the number of the heart-beats while the current was being used, also whether he had ever obtained paling of the face and dilatation of the pupils, phenomena which follow galvanization of the sympathetic when needles are used.

Dr. ROCKWELL replied that he had not made his observations during the application, but that subsequently such slowing had been demonstrated. Lowering of the pulse was also a very common result of general faradization.

Dr. GEORGE W. JACOBY considered exophthalmic goitre a rare disease. For eight or nine years he had seen in his dispensary six to seven hundred neurological cases a year. Not more than a dozen of these had been cases of exophthalmic goitre. The patients had been regular in attendance, and treatment had been persistent, but he had tried every means heralded without result. Sub-aural galvanization had been without effect upon the color or the pulse. He considered the disease a hopeless condition. Bodily and mental rest furnished about all which could be done. He had tried faradism according to the recommendation of Vigouroux, but also without result.

He thought the exophthalmos the least constant symptom. Where goitre was present one side of the neck was usually larger than the other. Some said that the right was always the larger. This he could contradict, as in a case which he had recently seen with Dr. Birdsall the enlargement had been equal upon both sides. Von Græfe's symptom was not always present. Tremor was often the first symptom. In one case in his experience tremor had existed for a year before the development of the other symptoms. At the end of the second year these had become well-developed, and bronzing of the skin also was present.

Vigouroux had stated that the electric resistance was diminished in all cases, and even in the commencement of the disease. This, if true, would be an important diagnostic point. In twenty cases published by Wolfenden, this lowered electrical resistance was present. Two of these cases are published in full. In one of the latter the resistance was only 300 ohms. It was mentioned that there was profuse sweating in this case. In the second the resistance was 200 ohms. Of this case it was said that there was clamminess of the surface and sweating. In the other thirteen cases the

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MARCH 29, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

SYSTEMATIZED ACTIVE EXERCISES IN NERVOUS AND MENTAL DISEASES.

DR. CHARLES K. MILLS, in a paper read before the Philadelphia County Medical Society, has called attention to the value of systematized active exercises in the treatment of nervous and mental disease. He alluded to the value of the writings of the Drs. Taylor, of New York, Drs. Benjamin Lee, Dujardin-Beaumetz and Schreiber, in regard to general medical gymnastics, and of Mr. Blaikie's two well-known books on physical culture to preserve health. Mills has found properly guarded gymnastic exercise of value in neurasthenia, hysteria, habit-chorea, neuritis, lateral spinal curvature, melancholia, idiocy, insanity, asthma, minor chorea, general nervousness, lithemia, diabetes, ataxias, paralyses, and, with special form of exercise, hæmiplegia, monoplegia, infantile paralysis, atrophy, aphasia and writer's or telegrapher's disease.

Of its use for the insane he says: "I believe insanity affords a great field for such treatment. In the first place, such exercises will do much toward improving the frequently deteriorated physical condition of the insane; secondly, they afford a method of calling out and improving the impaired mental faculties; and, thirdly, they constitute another valuable means of supplying to the insane that, which all alienists now agree is most important to them—occupation. By means of systematized exercises, the insane can be provided with an additional 'rational physiological outlet' for their morbid muscular energy, on the one hand, and, on the other, with a rational physiological method of calling them out of their muscular and general torpor. In the Insane Department of the Philadelphia Hospital, even patients, in the profoundest depression, could, by sufficient persistence, be aroused to the performance of some movements; others did moderately well; some very well. The difficulty of fixing the attention of these patients, and yet the possibility of doing it by sufficient effort has been clearly shown."

In the idiot schools, under Dr. Kerlin in Pennsylvania, and Dr. Brown in this State, regular gymnastics

have been of the greatest value; and at the insane asylum in Dixmont, Dr. Mills might have found an admirable illustration, if the daily gymnastic drill of ten years ago has been kept up, for the benefit to the patients was then very manifest.

It is impossible to follow all the details of this excellent paper, but it is all comprehended if one says that all people need exercise or some substitute for it, and the ill even more than the well. Dr. Mills recommends the complicated apparatus of Ruebsam, and the simple pulling weights of Reach & Dowd. In Boston, excellent pulleys and weights are sold at the low cost of four and six dollars, which have proved invaluable to many invalids and delicate people. In neuralgia, muscular rheumatism, constipation and the host of symptoms associated with what is known as poor health, as well as in more serious troubles, judiciously used under the general direction of a physician, these simple measures have often been of great service.

LUYS'S EXPERIMENTS ON THE ACTIONS OF MEDICINES AT A DISTANCE IN HYPNOTIZED SUBJECTS.

At one of the sessions of the Académie de Médecine, Paris, during the last half of the year that is past, M. Luys, of considerable reputation as an alienist and author of valuable treatises on the nervous system, reported a series of experiments with hypnotized subjects, in which remarkable results were claimed by simply holding, first near, then at a little distance from these subjects, sealed vials containing certain medicinal substances. Thus, a vial containing a small dose of sulphate of strychnia, placed near the back of the neck, would determine "bilateral contractures, with convulsive shocks and stiffness of the body, turgescence of the face and thyroid body." Atropine occasioned a stupefaction; a vial of alcohol in a few minutes "determined phenomena of drunkenness." The morphine vial caused different symptoms, according as it was placed on the left or the right side of the nucha: if placed on the left side, the subject became violently irascible and disposed to fight; if placed on the right, he was calm and tranquil as a summer eve. A large number of drugs was experimented with, all producing different and characteristic effects.

Such was the subject of a sober, somewhat lengthy communication presented to the Academy on the 30th of August. It is needless to say that the extraordinary statements of M. Luys were received with incredulity, if not derision, although the French mind is disposed to accept almost any absurdity connected with hypnotism.

At this meeting, a Committee of three was appointed by the President to examine the facts communicated by M. Luys, and report at a future meeting. This Committee, through their Chairman, reported the result of their investigations at the session of the Academy, March 6th.

From this communication it would appear that the scientific validity of M. Luys's experiments was rendered null and void by simple absence of the Baconian method of exclusion, as well as by what the late Dr. George M. Beard pointed out as a fruitful source of fallacy in testimony, unintentional collusion between the operator and the subject. Luys's experiments were repeated, and found to correspond to the statements made in his communication, but everything took place as if by a pre-determined plan, and arranged for the occasion; and when the Commission tried their own sealed vials, the contents of which no one knew but themselves, they either obtained no results at all, or no results that were characteristic, definite, and significant.

TRANSPORTATION OF THE WOUNDED.

ASSISTANT SURGEON JAMES E. PILCHER read a paper, March 21st, before the Military Service Institute at Governor's Island, New York Harbor, on "The Transportation of the Wounded." It was confined to the matter of removing wounded men from the field by human bearers, and the methods he described were illustrated by a squad of men whom he had trained. He especially advocated the carrying of stretchers in hands of bearers, instead of on their shoulders, as was common during the late war; and in this connection he called attention to the fact that General Stonewall Jackson was killed by the falling of one of the stretcher-bearers, who were carrying him with the stretcher resting on their shoulders.

Among those who discussed the paper and commended the views expressed were Surgeons Spencer, of the 23d Regiment; Cochran, of the 8th Regiment; and Atwood, of the 14th Regiment; and Dr. Lewis Pilcher, of Brooklyn, a brother of Dr. James Pilcher, who also served in the war.

THE SPONTANEOUS ATTENUATION OF ERYSIPELAS OF THE FACE.

JACCOUD has published in the *Semaine Médicale* a "conference" with the above title, in which he calls attention to a fact familiar to physicians who have had large experience with erysipelas: namely, that a first attack of facial erysipelas, provided it may have been one of considerable severity, while not conferring immunity from subsequent attacks, nevertheless attenuates the symptoms of a second attack. He reports several cases where, with intensity of the local symptoms (tumefaction of the face and scalp, followed by desquamation, erythematous angina, etc.), there was neither fever nor constitutional disturbance. In all these cases the "streptococcus erysipelatus" of Fehleisen was found in the erysipelatous patches.

He considers this fact an illustration not of the "attenuation of virus," but of that modification in the "culture soil" which takes place as a result of a first subjection to an infectious agent, and which makes

the subject, if not refractory altogether, at least exempt from the worst symptomatic effects when the morbid microbe has again invaded the organism.

THE AMERICAN PUBLIC HEALTH ASSOCIATION PRIZES.

THE successful essays for the prizes offered by Mr. Henry Lomb, of Rochester, for 1887 have just been printed. The subjects and the authors are as follows: "Healthy Homes and Foods for the Working Classes," by Victor C. Vaughan, M.D., Ph.D.; "The Sanitary Conditions and Necessities of School-Houses and School-Life," by D. F. Lincoln, M.D.; "Disinfection and Individual Prophylaxis against Infectious Diseases," by George M. Sternberg, M.D.; "The Preventable Causes of Disease, Injury, and Death in American Manufactories and Workshops, and the best Means and Appliances for Preventing and Avoiding Them," by George H. Ireland.

Mr. Lomb again offers, through the American Public Health Association, two prizes for the current year, on the following subject: "Practical Sanitary and Economic Cooking adapted to Persons of Small and Moderate Means"—one of \$500, and a second of \$200.

The judges are to be Prof. Charles A. Lindsley, New Haven, Conn.; Prof. George H. Rohé, Baltimore, Md.; Prof. Victor C. Vaughan, Ann Harbor, Mich.; Mrs. B. H. Richards, Boston, Mass.; Miss Emma C. G. Polson, New Haven, Conn.

The essay is expected to cover in the most specific manner methods of cooking, as well as carefully prepared receipts, for three classes: those of moderate means, those of small means, and those who may be called poor. For each of these classes, receipts for three meals a day for several days in succession should be given, each meal to meet the requirements of the body, and to vary as much as possible from day to day. One requirement will certainly demand original work: Formulas for at least twelve dinners, to be carried to the place of work, and mostly eaten cold, are to be given. Healthfulness, practical arrangement, low cost, and palatableness should be combined considerations. The object of this work is for the information of the housewife, to whose requirements the average cook-book is ill adapted, as well as to bring to her attention healthful and economic method and receipts.

Competition is open to authors of any nationality, but it is intended that these essays shall be essentially American in their character and application. The prizes are sufficiently liberal to call out honest and original work.

We are glad to notice increasing evidences of the realization among the well-to-do, of the importance of encouraging a knowledge of wholesome and economic methods of cookery among the people at large, and simultaneously a disposition to increase the opportunities for obtaining such a knowledge. The Industrial

School at the North End of Boston (having its origin in the liberality and zeal of a wealthy lady), which has just made its annual report, gives instruction in cooking, among other useful things, to a very large number of girls.

MEDICAL NOTES.

— Foreign exchanges state that the cause of the death of the late emperor of Germany was renal colic. The emperor had of late years suffered from several very severe attacks of this affection, which he bore with great fortitude, though suffering on each occasion from weakness attendant on the sleeplessness caused by the attacks.

BOSTON AND NEW ENGLAND.

— The last annual report of the Lowell Hospital gives the following statistics for the year 1887:

In Hospital, January 1, 1887, 18; males admitted, 108; females admitted, 156; total admissions, 264; total number treated, 282. Discharged, 243; died, 21; total number discharged and died, 264; remaining in Hospital January 1, 1888, 18. Per cent. of deaths to the number of patients treated, 7.4. Per cent. of deaths, excluding deaths within twenty-four hours of admission, 6.0. Largest number of patients in Hospital on any one day, 37. Smallest number of patients in Hospital on any one day, 11. The 282 patients treated remained in the Hospital 7,188 days during the year, an average length of stay of 25.49 days per patient.

— A Committee of the Trustees of the Johns Hopkins Hospital, of Baltimore, has been in Boston this week to examine the administrative working of its hospitals. The City Hospital, the Massachusetts General and the Children's Hospital were visited and the system of administration obtaining at each investigated. From Boston the committee goes to New York with the same object in view. The buildings of the Johns Hopkins Hospital are ready for occupancy and the Hospital will before long be open for the reception of patients.

NEW YORK.

— The annual dinner of the New York Polyclinic was held at Delmonico's, March 20th, with Dr. James B. Hunter presiding. This institution is in a flourishing condition, and has the names of 353 students (all graduates of medicine) on its books for the current year, a larger number than in any previous season.

— Mr. Henry Bergh, Jr., a nephew of the late Henry Bergh, has been elected President of the Society for the Prevention of Cruelty to Animals, in his uncle's stead.

— The Fassitt Bill, which places the Quarantine station on a more business-like basis by reducing the salary of the Health Officer of the port to \$10,000 per annum, cutting down the fees, and providing for the proper maintenance of the establishment from the

funds received from fees, has passed both houses of the Legislature, and received the signature of Governor Till.

Miscellany.

LAPAROTOMY FOR TUBERCULAR PERITONITIS.

DR. JOHN HOMANS reports in the *London Lancet*, February 11, 1888, two cases of laparotomy for ascites caused by tubercular peritonitis, in both of which laparotomy and free drainage were followed by a good recovery. One of these cases is reported in Dr. Homans's little book, "Three Hundred and Eighty-Four Laparotomies for Various Diseases." The second patient "was a school-girl, seventeen years old, of healthy appearance. Her complexion was pale. Her umbilical girth was thirty-four inches. . . . On opening the peritoneum, April 20, 1887, ascitic fluid ran out, and, on further investigation, the whole abdominal cavity was found to be studded with small, hard, whitish nodules. They were on the uterus, intestines, and parietal surface of the peritoneum, both ovaries, and Fallopian tubes. One tube thickly studded with tubercles, with its corresponding ovary, was removed. The peritoneal cavity was carefully sponged out, but the ascitic fluid seemed to re-accumulate so fast that a glass drainage-tube was put in, and the abdomen closed. . . . Only about an ounce of fluid in the twenty-four hours was obtained by the drainage-tube, and on the third day it was removed. The patient went home at the end of three weeks."

On the 28th of December, 1887, this patient was reported as free from abdominal troubles, fever, etc., and as having a good appetite and being in a fair state of health.

THE DELICACY OF THE SENSE OF TASTE.

MESSES. E. H. S. BAILEY AND E. L. NICHOLS, who have published a number of observations on matters connected with the taste-sense, presented an additional paper on the subject to the American Association for the Advancement of Science, at its meeting August, 1887. This paper is published in *Science*, March 23d, and from it we make the following extracts:

The method pursued in the following experiments was as follows:—

Solutions of known strength were made of the substances to be tasted; then, by successive dilutions, several series of solutions were made from these, each one in the series being of one-half the strength of the preceding one. The bottles containing these solutions, and several bottles of water, were placed without regard to order, and the person to be experimented upon was requested to separate them into their proper groups by tasting them. In each series the last solution was so dilute as to be beyond recognition. All unrecognized solutions were classified as water.

The following typical substances were chosen for the test. The strength of the initial solution of each is given below.

1. (Bitter) quinine, one part in 10,000 parts of water.
2. (Sweet) cane-sugar, one part in 30 parts of water.
3. (Acid) sulphuric acid, one part in 100 parts of water.
4. (Alkaline) sodium bicarbonate, one part in ten parts of water.
5. (Saline) sodium chloride, one part in 100 parts of water.

The attempt was made to include other substances,

as aromatics, in the test; but it was soon found that the odor betrayed their presence without the aid of the sense of taste.

Other investigators have added astringents as a sixth class, but these substances are so often recognizable by odor, color, or some special taste not purely astringent, that it was thought best not to include them.

Tests by the method above described were made upon 123 persons; 82 being male, and 46 female observers.

The following table shows the amount of each substance which could be detected by the average observer:—

Substances.	Male observers detected.	Female observers detected.
Quinine.	1 part in 392,000	1 part in 456,000
Sugar.	" " 199	" " 204
Acid.	" " 2,680	" " 3,280
Soda.	" " 98	" " 126
Salt.	" " 2,240	" " 1,980

From the above results the following conclusions are drawn by these observers.

1. The sense of taste is vastly more delicate for bitter substances than for any others. It is possible to detect quinine in a solution that is only $\frac{1}{392,000}$ the strength of a sugar solution, and the writers have previously shown that quinine is only $\frac{1}{10}$ as bitter as strychnine.

2. The order of delicacy is, bitter, acid, salt, sugar, and alkali.

3. The sense of taste appears to be more delicate in women than in men. This is true in the case of all the substances excepting salt. As we had found a similar difference in favor of female observers in an earlier and independent set of experiments, which agreed in every essential particular with the results of the present test, we do not regard it as an accidental difference, or as likely to disappear in more extended investigations.

Marked differences in the delicacy of the sense of taste of different individuals were met with in the course of these experiments. There were persons who could place in the proper class solutions containing one part of quinine in 500,000, and other substances in correspondingly high dilution, while some failed to detect solutions of more than three times the above strength. In how far this was due to education we are unable to say. Among the men examined were many who have been accustomed to handling and recognizing drugs and medicines, and yet even these were frequently surpassed by female observers who had no such training.

In some previous experiments upon the sense of smell, of which an account appeared in *Nature* (*loc. cit.*), we noted almost as marked superiority on the part of male observers.

In a few cases the ability to detect a dilute sweet was accompanied by a lack of ability to detect dilute bitters. This peculiarity was, however, far from being a general one.

As quinine is so largely used as a medicine, especially in the Western States, it was thought that its habitual use might dull the sense of taste for this particular substance. Among the observers subjected to our experiments, the use or disuse of quinine seemed to have had no especial influence.

OBITUARY. WILLIAM B. GOLDSMITH, M.D.

DR. WILLIAM B. GOLDSMITH died of pneumonia at the Butler Hospital, in Providence, on the 21st inst., aged thirty-four. He had not been quite well since a professional visit to New Orleans, where he had a febrile attack last summer, and several times of late he had spoken of feeling ill. Although the initial chill was on the 14th, he kept about, supposing that he had taken a severe cold, until the 17th. After that he grew rapidly worse, the dusky color of the skin, the weak action of a heart, which had long caused him some uneasiness, and the rapid increase in the difficulty of respiration showing clearly to him quite soon that "the chances were against him." Although wishing to live, he regarded his death with a calmness and courage which one might well envy him, and made every preparation for it to the least detail, remembering each and all of his friends with that kind thoughtfulness of others, which, well, or ill, he never forgot.

At school, in college at Amherst, at the Medical School in New York, he was faithful, shy and reserved. After a short service as hospital interne he was appointed junior assistant at the Bloomingdale Asylum, where he afterwards became senior, under Dr. Chas. H. Nichols, having previously been with Dr. Chapin at the Willard Asylum. He was also, after his experience in two asylums in this country, a volunteer assistant of Dr. Clouston, in Edinburgh, and in the West Riding Asylum, as it was splendidly organized by Crichton Browne, and later he temporarily left his duties as superintendent to study a year with Westphal and Krafft-Ebing and others in Europe. A better training one could scarcely have. Dr. Chapin had few equals in the management of asylums. Dr. Nichols held the first rank in the observation and analysis of mental phenomena, and Dr. Clouston had no superior in the clinical study and treatment of the insane.

That Dr. Goldsmith made the best use of his opportunities is attested by his valuable work as physician and superintendent of the Danvers Asylum, where he was appointed at the age of twenty-eight, and of the Butler Hospital, where he succeeded the late Dr. Sawyer two years ago. It is not too high praise to say that no man in this country is doing better work in mental disease than he did, that the treatment of the insane has become more liberal and progressive throughout New England for what he has accomplished, and that no one could look forward more confidently to the first position in his specialty in this country.

Personally, Dr. Goldsmith was a gentleman in the highest and best sense of that much-abused word. No one who knew him well can ever forget, back of his formal, shy and sensitive exterior, that rare courtesy and considerate kindness which never failed him. He was honest throughout, both morally, and, which is more difficult, intellectually. In his standards for the conduct of life, and in his daily action upon them he did not disappoint his most critical friends.

Correspondence.

TRADE OR PROFESSION.

Boston, 235 Marlborough St., March 24, 1888.

MR. EDITOR,—A recent issue of your valuable Journal contained an article entitled "Trade or Profession," in which attention was called to an address by H. C. Merriam, D.M.D., delivered before the Maine Dental Society.

In your article and in Dr. Merriam's address, the difference between a trade and a profession is sharply drawn and the position of dentistry and its relation to medicine is well pointed out.

Not only is it true that while the practice referred to of obtaining patents and accepting royalties for inventions, which should be freely given to the profession, is permitted to continue unrestrained, dentistry cannot claim to be a branch of medicine, but it is equally true that it cannot claim

to be a profession at all. But I hasten to say that by no one is the practice more severely condemned than by the better class of dentists, nor would such men withhold their knowledge or their inventions, or stoop to accept a royalty for the same, more quickly than would a similar class of physicians or surgeons.

Already have our dental societies condemned the practice of patenting inventions and have, in several instances, refused admission to those who insisted upon pursuing such a course, and day by day increasing liberality in sharing knowledge is shown and professional jealousy and discord are frowned upon.

As in the medical profession, many men after graduating from reputable colleges fall into irregular methods and

adopt means for obtaining practice and gaining wealth not in keeping with their code of ethics, so it is true that many men practicing dentistry will do the same, but it cannot be doubted that there is a sincere and earnest desire among educated dentists to ennoble the calling, to increase its usefulness and to place it upon a higher plane than it has hitherto occupied.

Many men now begin the study of dentistry by a preliminary course in medicine, and as knowledge increases and educated men take up the work, it is hoped that the time will soon come when dentistry will be recognized not only as a profession, but as an important branch of medicine. Yours very truly,

SAMUEL A. HOPKINS, M.D., D.D.S.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 17, 1888.

Deaths reported 2,226; under five years of age 751; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 312; acute lung diseases 369, consumption 288, diphtheria and croup 102, scarlet fever 41, diarrheal diseases 36, typhoid fever 27, measles 26, whooping-cough 21, cerebro-spinal meningitis 19, malarial fever 16, puerperal fever 10, erysipelas nine, small-pox five. From typhoid fever, Philadelphia 11, Milwaukee seven, District of Columbia three, New York two, Boston, Baltimore, Pittsburgh and Newburyport one each. From measles, Baltimore nine, New York eight, District of Columbia seven, Pittsburgh and Milwaukee one each. From whooping-cough, New York six, Philadelphia and Baltimore three each, Pittsburgh and Cambridge two each, Boston, New Orleans, District of Columbia, Milwaukee and Haverhill one each. From cerebro-spinal meningitis, New York six, Philadelphia and Fall River three each, Chelsea two, New Orleans, Pittsburgh, Milwaukee, Lynn and Gloucester one each. From malarial fever New York nine, District of Columbia and Milwaukee two each, Philadelphia, Baltimore and New Orleans one each. From puerperal fever, District of Columbia three, New York and Boston

two each, Baltimore, Milwaukee and Taunton one each. From erysipelas, Boston five, New York three, Philadelphia one.

In 21 cities and greater towns of Massachusetts with an estimated population of 1,052,435, the total death-rate for the week was 22.58 against 24.37 and 24.03 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending March 3d, the death-rate was 21.5. Deaths reported 3,875; infants under one year of age 967; acute diseases of the respiratory organs (London) 488, whooping-cough 136, scarlet fever 59, measles 42, fevers 39, diphtheria 37, diarrhoea 28, small-pox (Sheffield 21, Leeds, Manchester, Nottingham and Bristol one each,) 25.

The death-rates ranged from 34.2 in Blackburn to 13.4 in Sunderland; Birkenhead 18.2; Birmingham 18.9; Bradford 14.3; Halifax 23.4; Hull 19.3; Leeds 24.2; Liverpool 23.5; London 21.9; Manchester 25.7; Nottingham 20.1; Oldham 24.2; Sheffield 24.7.

In Edinburgh 21.1; Glasgow 27.6; Dublin 34.0.

The meteorological record for the week ending March 17, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.	
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Daily Mean.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Duration, Hrs. & Mins.	Amount in Inches.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—The annual meeting of the Society will be held at the Medical Library, 19 Boylston Place, on Monday evening, April 2, 1888, at 9 o'clock. Election of officers for the ensuing year, election of new members. Readers: Dr. Bitely, "One, Possibly Two Cases of Graves Disease," Dr. Jelly, "Case of Tetany." Case of General Paralysis of Ten Years' Duration; Death from Heart Disease. CHARLES P. STRONG, M.D., Secretary.

SEFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.—There will be a meeting of this Section on Wednesday evening, April 4th, at 8 o'clock. Dr. M. H. Richardson will report "A Case of Nephrography." Dr. D. W. Cheever will read a paper on "The subsidence of Pseudo-fibrous tumors under the Use of Alterative Medicines." Dr. Royal Whitman will read a paper entitled "Observations on Forty-Five Cases of Flat-Foot, with Particular Reference to Etiology and Treatment." G. H. MONKS, M.D., Secretary.

DEATH.

Died at Providence, March 21st, of pneumonia, William B. Goldsmith, M.D., at the age of thirty-four.

Practical Microscopy: A Course of Normal Histology for Students and Practitioners of Medicine. By Maurice N. Miller, M.D., Director of the Department of Normal Histology in the Loomis Laboratory, University of the City of New York. Illustrated with one hundred and twenty-six photographic reproductions of the author's pen-drawings. New York: William Wood & Co. 1887.

A Practical Treatise on the Medical and Surgical Uses of Electricity, including Localized and General Faradization, Localized and Central Galvanization, Franklinization, Electrolysis and Galvano-Cantery. By George M. Beard, A.M., M.D., and A. D. Rockwell, A.M., M.D. Sixth edition. Revised by A. D. Rockwell, M.D., with nearly two hundred illustrations. New York: William Wood & Co. 1888.

A Manual of the Physical Diagnosis of Thoracic Diseases. By E. Darwin Hudson, Jr., A.M., M.D., late Professor of General Medicine and Diseases of the Chest in New York Polytechnic; Physician to Bellevue Hospital, etc. One volume, octavo. One hundred and sixty-two pages. Nearly one hundred illustrations. New York: William Wood & Co. 1887.

Therapeutics of Circulatory Derangements, Weakness of the Heart Muscle, Insufficient Compensation in Cardiac Failure, Fatty Heart and Obesity, Alterations in the Pulmonary Circulation, etc. By Prof. J. M. Oertel, M.D., of Munich. With thirty-seven illustrations. Translated by Edward J. Edwards, M.D., M.R.C.P., London. New York: William Wood & Co. 1887.

Second Series Photographic Illustrations of Skin Diseases. Forty-eight quarto plates (seventy-six photographic cases from life), accurately colored by hand. An atlas and text-book, two hundred and eight pages. By Dr. George H. Fox, Professor Diseases of the Skin, College of Physicians and Surgeons, N. Y. Parts III and IV. New York: E. B. Treat. 1888.

Lecture.

CARTWRIGHT LECTURES. THE GENERAL PATHOLOGY OF FEVER.

BY WILLIAM H. WELCH, M.D.,
Professor of Pathology, Johns Hopkins University, Baltimore.

LECTURE I.

THERE is no subject in medicine of more general and varied interest than fever. The practitioner in every department of medicine, the pathologist and the physiologist, are equally interested in the investigation of the nature and effects of fever. Even the physicist and the chemist, who are not directly concerned with medical science, have lent their aid to the study of animal heat and its disorders. The history of opinion regarding fever is in great part the history of medicine itself, for no feature of the great systems of medicine from Hippocrates and Galen to the present century so characterizes these systems as the views held concerning the nature of fever. In consequence of the importance of the subject and of the number and ability of those engaged in its investigation it might be supposed that no chapter in medical science would be better understood than that pertaining to fever. That such is not the case is due to the fact which is becoming more and more evident that the reaction of the animal system which we call fever is dependent upon the most fundamental and essential properties of protoplasm and of nerve energy. In proportion as our knowledge of these properties increases and becomes more accurate, we gain a clearer insight into the complicated processes involved in the production of fever.

I should hardly have selected for this course of lectures a subject where so many problems remain unsolved, and which must necessarily be presented in so fragmentary a form, were it not that in all ages the opinions held concerning the nature of fever have controlled measures employed in its treatment. In proof of this one need not go back to the time when fever was regarded as an almost conscious struggle of an animal with a noxious principle, in which struggle the physician was to interfere as little as possible, or to the time when fever was supposed to result from morbid humors which the physician should aim to eliminate by the production of a critical discharge, or to the period when the treatment binged upon the belief either in the sthenic or the asthenic nature of fever. In our own time the treatment of fever is intimately connected with the answers variously given to such questions as whether fever aids in the elimination or destruction of infectious agents concerned in its production; whether increased waste of tissue is a constant condition and a source of danger in fever; what part is played by infection, and what part by elevation of temperature in causing the grave symptoms of fever; what, in addition to lowering of temperature, are the effects of so-called antipyretic measures of treatment?

I need hardly say that the subject of these lectures relates to fever as a condition common to all febrile diseases. Some writers understand by the term fever used in this sense merely abnormal elevation of temperature, others elevation of temperature and the symptoms directly caused by this, and still others a

complex of symptoms of which increased temperature is the most prominent symptom, but not necessarily the cause of the others. In considering the general pathology of fever it is convenient to adopt the last meaning, although it would doubtless be less confusing if the word fever were applied only to abnormal elevation of temperature.

Increased temperature being the dominant and essential symptom of fever, all discussions as to the nature of fever center around the question: How is febrile rise of temperature produced? It is to the consideration of this question that I first invite your attention. As there are other aspects of fever which I wish to discuss, it will be necessary to present the matter belonging to this division of the subject in as succinct a form as is compatible with clearness. Twelve years ago Burdon-Sanderson brought together in an admirable critical review the results of investigations upon this subject up to that period. Since that time important additions have been made to our knowledge of the mode of production of fever.

In the wonderful preservation of a nearly constant temperature which characterizes in health the warm-blooded animals, three factors are concerned; namely, the production of heat within the body, the loss of heat within the body, and the regulating mechanism by which the varying heat-production and heat-loss are so balanced that the internal temperature remains practically constant. It is theoretically possible that the rise of temperature in fever may be due to the disturbance of any one or more of these factors. It becomes necessary, therefore, to consider the behavior of heat-production, of heat-loss, and of the regulating mechanism in fever.

We will begin with a consideration of the production of heat in fever. The amount of heat produced by the body is estimated by two methods, one known as direct calorimetry, the other as indirect calorimetry. In the method of direct calorimetry the animal is placed in a closed ventilated box, surrounded on all sides by a compartment containing water, or air, and the amount of heat discharged from the body is determined by the quantity of heat imparted to the surrounding water or air. If the temperature of the animal remain unchanged during the period of observation, the heat-production is equal to the heat-loss; if the temperature rise or fall, the amount of heat corresponding to this change of temperature — an amount determined by multiplying the weight of the animal by its specific heat, and by the number of degrees of altered temperature — is added to or subtracted from the quantity of heat imparted to the calorimeter. Time will not permit me to enter into experimental details in this connection; it must suffice to say that the method of direct calorimetry necessitates the introduction of a number of corrections which cannot be determined with absolute accuracy, so that the results obtained are of relative rather than of absolute value.

Hitherto the estimation of heat-production in fever by determining the entire amount of heat liberated from the body has been made only upon animals in which fever has been artificially produced. The most elaborate researches of this nature are those of Senator and of Wood.² The experiments of Wood are of the

¹ Delivered before the Alumni Association of the College of Physicians and Surgeons, of New York, March 29, 1898.

² Senator. *Untersuch. ub. d. Fieberhaften Process*, Berlin, 1878. Wood. *Fever; a study in Morbid and Normal Physiology*, Philadelphia, 1895.

greater value, because he extended his observations over longer periods of time.

In four of the seven calorimetric experiments of Wood on different febrile dogs, comparison can be made of the amount of heat produced hourly in fever with that produced by the same animal when fed and when in a state of hunger. During the period of fever the animal was also in a condition of hunger. I have computed from Wood's tables that the average hourly heat-production during seven days, described as first and second fever days, is a little over twenty-three per cent. greater than that produced by the healthy animal during a state of hunger, the minimum excess being one per cent., and the maximum 55.5 per cent. If a comparison be made of different periods during the existence of fever there are found to be even greater fluctuation in the amount of heat production than these figures would indicate, this amount being sometimes more than double that in hunger, and sometimes considerably less than the average production in hunger. Moreover, these experiments show no definite relation between the height of the temperature and the amount of heat produced, nor is it possible to deduce from them any relation between heat-production and the different stages of fever, such as the more recent calorimetric experiments of Wood, Reichert and Hare, appear to show, and which will be described later. An important outcome of these, as well as of all similar calorimetric experiments, is that although the heat-production of an animal in fever is greater than that of one under like conditions of nourishment, it is, as a rule, less than that of the same animal upon a full diet.

There are many reasons which make it important to control the experimental results obtained from animals in fever by corresponding observations of human beings. The agents used in producing experimental fever have been generally putrid fluids or pus, the injection of which causes sometimes diminution instead of elevation of temperature. When fever is thus produced it is usually of short duration, and of only moderate intensity, the rise of temperature being rarely more than four degrees, and sometimes not more than one degree Fahrenheit. Moreover, a large part of the important rôle played by the skin in the regulation of the bodily temperature in man is assumed by the lungs in these animals.

Complete calorimetric observations of human beings in fever, encountered difficulties which have not yet been overcome. The imperfect or incomplete methods employed by Liebermeister³ and by Leyden⁴ in determining the heat-production of human beings in fever, justify the inference that this production is increased, and apparently as a rule to a greater extent than in animals, but they do not warrant positive conclusions as to the quantity of heat produced.

We turn now to the results regarding febrile production of heat obtained by what has sometimes been called indirect calorimetry. Inasmuch as the heat energy of the body is the result of chemical changes of its proteins, fats and carbo-hydrates, it is evident that if we know the kind and the amount and the heat value of the substances consumed in a given time within the body, we can compute their heat-production. These chemical changes so far as their final

products are concerned, are processes of oxidation. The heat values of the substances consumed in the body, were determined, first by Frankland and more recently with greater accuracy by von Rechenberg, Danilewsky and Rubner. The investigations of Pettenkofer and Voit, have shown that in hunger almost exclusively, fats and proteins are oxidized, and that in this condition by determining the amount of oxygen absorbed and of nitrogen and of carbon excreted, we can estimate the quantity of fat and of proteid substance oxidized during the period of observation.

Physicians of past centuries regarded increased consumption of the material of the body in fever, as so evident that it needed no especial demonstration, and after Lavoisier made apparent the sources of animal heat, it was accepted almost unquestionably until the last quarter of a century, that fever is essentially a process of increased combustion or oxidation. The immense historical importance of the promulgation in 1863 of Traube's theory, which denied the dependence of fever upon increased production of heat, is that this theory has led to a careful inquiry into the grounds of beliefs hitherto generally accepted, and to the demonstration of the unsatisfactory nature of the evidence hitherto thought to be conclusive.

The striking loss of weight of most fever patients, is, as is well-known, a fact of great clinical importance. Weber and Finkler have demonstrated that animals in fever lose weight more rapidly than healthy animals in hunger, and although observations on human beings with reference to this point are not concordant in their results, there can be little doubt that the tendency of fever is to cause a greater loss of weight than can be explained simply by insufficient nutriment. This tendency, however, may be masked by the retention of water within the body, as the investigations of Leyden and others have shown. While, therefore, the studies of the loss of weight in fever leave no doubt that there is increased destruction of tissue in this condition, we cannot consider this loss as an accurate measure of the increased destruction, nor, without further knowledge, as an indication of increased oxidation, still less as proof of excessive production of heat.

It was for a long time believed that the excessive excretion of urea in fever, afforded satisfactory evidence of increased oxidation and of greater production of heat. We now know, especially from the researches of A. Fraenkel, that this is so far from being true, that we can explain the excessive elimination of urea better upon the assumption of diminished than of increased oxidation of tissue. In certain pathological conditions, notably phosphorus poisoning, the amount of urea excreted may be increased more than three-fold, notwithstanding, or, as Fraenkel believes, in consequence of diminished absorption of oxygen and elimination of carbonic acid. It can, moreover, be computed that even without any diminution of the respiratory gases the discharge of urea may be increased without greater production of heat. While, therefore, the enormous increase in the discharge of urea in fever, sheds valuable light upon a most obscure subject, the nature of febrile metabolism, it does not, regarded by itself, afford us any information as to the production of heat.

Failing to find satisfactory proof of increased oxidation in the loss of weight of the body, or the excessive excretion of urea in fever, attention was then

³ Liebermeister. *Handb. d. Path. u. Therap. d. Fiebers*, Leipzig, 1877.

⁴ Leyden. *Deutsches Arch. f. Klin. Med.*, Bd. 5.

directed to the elimination of carbonic acid, an excretory product which bears a much closer relation to the production of heat than does urea. Immense importance has been justly attached to the determination of the amount of carbonic acid excreted by an individual in fever. No point in the whole battleground of fever pathology has been more hotly contested than whether increased production of carbonic acid is an essential part of the febrile process. The first investigators of this question, Leyden, Liebermeister, Senator, contented themselves with the determination of the amount of carbonic acid eliminated by an individual in fever and in apyrexia. There are several considerations which greatly diminish the value to be attached to the mere estimation of carbonic acid excreted without simultaneous determination of the amount of oxygen absorbed. As has been urged by Senator and with especial clearness by Pflüger, increased discharge of carbonic acid does not necessarily imply increased production of the same. The discharge of carbonic acid varies, independently of its production, with the rhythm and depth of respiration and with the temperature and the alkalinity of the blood, all factors which are altered in fever in such a manner as to favor increased liberation of carbonic acid. It is true that the influence of these factors would cause increased discharge of carbonic acid out of proportion to its production only for a limited period, and that the prolonged increase in the amount of carbonic acid discharged in fever, which has been found by several observers, can hardly be interpreted otherwise than in favor of increased production. There is another point which detracts still further from the value of exclusive determinations of the quantity of carbonic acid discharged, and this is that it makes a great difference so far as the production of heat is concerned whether the carbonic acid is the result of oxidation of carbo-hydrates, of fats or of proteids, a difference amounting, according to Rubner, to 29.5 per cent., or if only the proteids and fats be considered to over 20 per cent. In investigations of nutrition it is now known to be of the utmost importance to determine the so-called respiratory quotient, that is, the ratio between the amount of carbonic acid discharged and that of oxygen absorbed. This quotient varies in a definite way with the kind of material oxidized in the body, and an accurate knowledge of it would enable us to draw conclusions as to the substances consumed in fever.

The investigations which have been published within the last few years upon the absorption of oxygen, as well as the discharge of carbonic acid in fever, are to be ranked as most valuable contributions to our knowledge of fever. The first estimation of trustworthy methods of the amount of oxygen absorbed, and of carbonic acid excreted in fever, was made in Pflüger's laboratory by Colasanti upon a guinea-pig, and was published in 1877. Since that time two careful and elaborate researches upon this subject have been made, the one by Finkler, and the other by Lilienfeld.⁶

These experimenters found that in fever there is increase of the amount both of oxygen absorbed and of carbonic acid excreted. Making comparison with healthy animals, under the same condition of nutrition, Colasanti found that the increase in the absorption of oxygen amounted to 18%, and in the excretion

of carbonic acid to 24%. Finkler, whose experiments were made also upon guinea-pigs, found under varying conditions of external temperature the average febrile increase of oxygen to be 13.8%, and of carbonic acid, 13.3%; and Lilienfeld, who experimented on rabbits, found the average increase of oxygen to be 15.9%. The statement of these averages gives an incomplete conception of the oxidation in fever, as they are derived from all stages of fever and varying elevations of temperature. No constant proportion was found to exist between the height of the temperature and the amount of oxidation. On the other hand, a relation was observed between the oxidation and the stages of fever; namely, the initial stage, with rising temperature; the acme, with constant high temperature; and the defervescence, with falling temperature. During the period of rising temperature oxidation was increased, and in this stage Finkler found the highest percentages, amounting to 36.6% in the increase of oxygen, and 37.6 of carbonic acid. There were, however, marked fluctuations in this stage, both in the temperature and the amount of oxidation. In the stage of constant high temperature such high percentages were not noticed, and the fluctuations were less marked. The processes of oxidation, according to Lilienfeld, are increased on the average less in the acme than in the initial stage of fever.⁶ During defervescence of the fever the increasing oxidation falls, and may sink below the normal. Taking a broad view of these stages, we may say, therefore, that the periods of rising, constant, and falling temperatures in fever correspond to the periods of rising, constant, and falling oxidation, but we must bear in mind that the fluctuations in oxidation are much greater than, and bear no constant relation to those of temperature, so that in each period there are times when oxidation may rise or fall most decidedly without corresponding changes of temperature.

Inasmuch as these experiments have shown that the increased excretion of carbonic acid in fever is accompanied by increased absorption of oxygen, and, as will be explained presently, that the respiratory quotient, if it changes at all, sinks, it is evident that we need not discard experiments in which only the amount of carbonic acid excreted has been estimated by good methods. The most accurate of these experiments are those of Leyden and Fraenkel upon febrile dogs.⁷ They found that, without exception, carbonic acid is excreted in larger amount in fever than in health under the same nutritive conditions, the excess amounting sometimes to 70%, and in general being larger than in the experiments which have been previously considered. The earlier and meritorious experiments of Senator upon this point did not give uniform results, and he felt justified in concluding that there is no evidence of increased production of carbonic acid in fever. Subsequent experiments with far more accurate methods have demonstrated the incorrectness of Senator's conclusions. It may be well to call to mind that Burdon-Sanderson's deductions, which have naturally had great influence among physicians here and abroad, were based in great part upon the data derived from Senator's experiments.

Hitherto the methods employed in studying the respiratory gases of human beings in fever have not

⁶ In the period of rising temperature there was an increase of oxygen absorbed of 27%, in the acme of 14.9%.

⁷ Leyden and Fraenkel. Virchow's Arch., Bd. 76.

⁵ Colasanti, Pflüger's Archiv., Bd. XIV. Finkler, *Ibid.*, Bd. XXIX. Lilienfeld, *Ibid.*, Bd. XXXII.

approached in accuracy those used in the experiments described. If the discordant results of Wertheim, which were obtained by methods manifestly very inaccurate, be discarded, all other investigators have observed augmented discharge of carbonic acid in human beings. Leyden found an excess of 50% in the febrile discharge of carbonic acid, and Liebermeister, whose observations were made chiefly on cases of intermittent fever, found an excess of 30% to 40% in the period with rising temperature, and of 19% to 31% in the acme of the fever. During the defervescence of the fever the excess of carbonic acid discharged diminished, and sometimes wholly disappeared. In one instance in which the determination was made during the rigor of intermittent fever, the carbonic acid excreted was two and one-half times the normal amount, an excess so enormous that it was undoubtedly due in great part to the muscular movements which attended the chill.

Although we cannot consider these figures as absolutely accurate, they indicate clearly that in human beings, as well as in animals, fever is characterized by increased oxidation, and apparently that, as a rule, in man the excess of oxidation is greater than in the experimental fever of animals. This was to be expected, as it is difficult to produce experimentally in animals anything approaching in intensity the well-marked fevers of human beings.

As the result of these laborious researches, we may consider it established that increased oxidation is a part of the fever process. It has been claimed that this augmented oxidation is simply the result of the elevation of temperature, but it can be proven that this is not true. Plüger has demonstrated that the processes of oxidation are more active at high than at low temperatures of the body, and he has also established the increment of oxidation which corresponds to each degree of rise of temperature. By means of these data, Finkler has computed that in guinea-pigs the febrile elevation of temperature of 1° C. could cause an increase of the absorption of oxygen of only 3.3%. Moreover, Lilienfeld found decided increase in the processes of oxidation before there is any marked elevation of temperature, and all the experiments have rendered it quite evident that there is no such relation in fever between the height of the temperature and the energy of oxidation, as would be expected if the augmented oxidation were merely the result of the increased temperature.

There is no reasonable doubt that the more energetic oxidation which we find to be an essential part of the process of fever indicates increased production of heat. Exactly what amount of heat-production corresponds to the increased oxidation we cannot know until the kind and the quantity of substances oxidized in fever have been determined. It is to be regretted that no experiments have been made in which the amount of nitrogen excreted has been determined at the same time with the estimation of the oxygen absorbed and of the carbonic acid discharged. These data would enable us to form some estimate, although not an accurate one, of the amount of heat-production corresponding to the oxygen absorbed, unless very different laws from those in health control the oxidation processes of fever.

Mention has already been made of the importance of determining in fever the respiratory quotient or the ratio between the carbonic acid discharged and the

oxygen consumed. A few words will make this clear. It is well known that under ordinary circumstances in health not all of the oxygen consumed reappears in the carbonic acid discharged. This indicates that a part of the oxygen absorbed is used in other oxidations than those resulting in the production of carbonic acid. According to the extent of these other oxidations, therefore, the respiratory quotient must vary. It is probable that these oxidations of which carbonic acid is not a product result at least in part in the formation of water, which is therefore one of the excretory products of the body as has been urged especially by Prof. Austin Flint. The influence of various circumstances upon the respiratory quotient has been studied, but what especially concerns us here is that in hunger this quotient sinks, which is to be expected from the fact that in this condition almost exclusively fats and proteids are oxidized. We evidently possess in the determination of the ratio of carbonic acid discharged to the oxygen consumed a means of reaching a conclusion as to a cardinal point in the pathology of fever; namely, whether the processes of oxidation in fever conform to the laws which govern them in health, and particularly whether as has been often asserted, unusual or incomplete products of oxidation are formed to any considerable extent in fever. Colasanti and Lilienfeld found that the respiratory quotient in their fevered animals did not vary from that of healthy animals under similar nutritive conditions. Finkler observed that the respiratory quotient fell in fever somewhat more rapidly than in hunger, and this he explains by the more active oxidation in fever. All three experimenters reached the conclusion that the substances oxidized are the same in fever as in health, and that other than the normal products of combustion are not formed in fever in any considerable amount. That the metabolism in fever does differ in at least one important respect from that in hunger is evident from the excessive amount of urea excreted in fever, but considerable variations in the disintegration of albuminous material may occur without much change in the respiratory quotient.

The only determinations of the febrile consumption of oxygen and discharge of carbonic acid in man are those of Wertheim and of Regnard. Both investigators found a decided diminution of the respiratory quotient. The method employed by Wertheim was so defective that no confidence can be placed in his results. The experiments of Regnard⁸ are presented with great neatness, but his results on other points differ so much from those obtained by trustworthy physiologists and by better methods that we cannot accept his conclusions as to the respiratory quotient in fever without confirmation. Regnard found in all fevers which he studied a most marked diminution of the respiratory quotient. If this were true, it would follow that in fever a much larger part than in health of the oxygen consumed is employed in other oxidations than those yielding carbonic acid. This would confirm the widely accepted belief that water and products of incomplete oxidation are formed in excessive amount in fever.

From the unfortunate discrepancy of these results it is evident that the knowledge which we now possess of the processes of oxidation in fever is not sufficient to enable us to form an accurate estimate of the

⁸ Regnard. *Recherches Exp. sur les Variations Pathologiques des Combustions Respiratoires*, Paris, 1878.

heat-production. In hunger from one-fourth to one-third of the absorbed oxygen is available for combination with hydrogen to form water, the remainder uniting with carbon to form carbonic acid (Regnault and Reiset). If in fever the same ratio exists then the excess of heat-production would be proportionate to the excess of oxygen absorbed, assuming that the substances oxidized are the same in both conditions; if, however, as Regnard's experiments indicate, a larger proportion of oxygen is available in fever for the oxidation of hydrogen, then the increment of heat-production would be still greater, for the same amount of oxygen produces more heat when employed in the oxidation of hydrogen than in that of carbon. It is also to be considered that the same quantities of hydrogen and of carbon in their oxidation yield varying amounts of heat according to the chemical compounds in which they are contained, and we cannot say positively whether the compounds oxidized are the same in fever as in health under like conditions of nutrition. Upon the whole, the weight of evidence is in favor of the view that the excess of heat-production in fever is approximately proportionate to the increase in the consumption of oxygen, but it would be rash to assert this positively. It is evident that in fever, ordinarily a much smaller amount than in health, of the energy resulting from chemical process is transformed into external mechanical work, so that relatively more remains in the form of heat.

In connection with this discussion of the possibility of unusual sources of heat in fever may be mentioned an hypothesis which has been advanced with much ingenuity by Dr. Ord.⁹ This hypothesis is based upon the assumption, which is probable enough, that there are in the body chemical processes in which heat energy is transformed, or rendered latent. These processes are thought to be chiefly those concerned in the building up of tissue. It is argued that inasmuch as the construction of tissue is manifestly in abeyance in fever, the amount of heat in the body may be increased, not only by disintegrative processes, but also by "the persistence in the form of heat of energy which should have taken another form." That these building-up processes influence decidedly the amount of heat produced in the developing ovum has been demonstrated by d'Arsonval's calorimetric determination that the egg during incubation absorbs heat, notwithstanding the consumption of oxygen, and the excretion of carbonic acid. This fact, which might have been predicted, certainly does not justify us in refusing to attach calorimetric value to the determination of the respiratory gases and the urinary nitrogen. From the little we know of these constructive processes in human beings, we should infer that the amount of energy in the form of heat which they appropriate bears only a very small ratio to the total heat-energy set free by heat-producing processes, so that their cessation would not bring a large increment to the heat of the body. Moreover, these constructive processes are also in abeyance, although doubtless to a less extent, in starvation with which experimental fever is usually contrasted as regards heat-production and heat-loss. It is not probable that any extraordinary difference in the behavior of the processes of tissue building in fever and in starvation can occur without affecting the respiratory quotient. For the present, therefore, we can not attach any great import-

ance, so far as the increase of heat-energy in fever is concerned, to the inactivity of heat-absorbing processes.

We have gone over now the evidence which, in my judgment, establishes the fact that there is increased production of heat in fever. The same conclusion is reached also by the study of the loss of heat from the body in fever. That fever is accompanied by increased production of heat and by more active combustion has been in all ages the belief of the majority of physicians. This belief, however, has been rather instinctive than based upon actual demonstration. It has been tested by investigators of great ability, and on the ground of scientific observations. For these reasons, and on account of the importance of the subject, it has seemed to me desirable to present to you the exact evidence, although many of its details, I fear, may have wearied you. We have learned, moreover, certain facts concerning febrile thermogenesis, which the mere observation of fever patients does not render so apparent. We have found that there is no definite relation between heat-production and the height of the temperature, so that we may have excessive thermogenesis with low as well as with high temperatures. There appears to be, however, a relation between the stages of fever and heat-production, this being in spite of remarkable fluctuations, greatest in the initial stage, and least in defervescence. Although, for reasons which have been mentioned, and others might have been adduced, we can attach hardly an approximate value to figures which purport to give the actual heat-production in fever, still, unless far more serious errors than seems possible inhere in the methods of direct and of indirect calorimetry, we can draw one important conclusion. This is that while an individual in fever produces more heat than he would in health under similar conditions as to food and muscular movements, he does not produce, necessarily, in fever, more heat than he would in health on a full diet. And it is certain that he usually produces far less heat in fever than he often does under circumstances which normally increase heat-production, such as a cool environment and muscular exercise. That one in health, with little or no change of temperature, may produce twice or more the quantity of heat which he produces in fever, makes it plain that it is impossible to explain febrile rise of temperature simply on the basis of increased thermogenesis, or what probably comes to the same thing, of increased oxidation. That in health vastly increased heat-production may occur with comparatively little change of temperature is, of course, due to the fact that the dissipation of heat is proportionately increased. It is self-evident, and, so far as I know, has never been disputed, that in fever the equilibrium is so disturbed that heat-loss does not correspond to heat-production as it should in health. This disturbance of equilibrium can be brought about in various ways, and it is only by the determination of the actual heat-production and heat-loss in fever that we can say in what direction the balance is disturbed.

We have found that the production of heat is increased in fever when the comparison is made with like conditions of nourishment and of environment. It is obvious that the total loss of heat can not equal the total production of heat during the period of febrile rise of temperature.

As is well known, most of the heat of the body is

⁹Ord. *British Med. Journal*, 1885, Vol. II.

liberated from the skin, and from the lungs; from the former by radiation and conduction, and by the evaporation of moisture and from the latter by evaporation of moisture and warming the respired air. It has been estimated that in man about eighty per cent. of the total heat-dissipation is from the skin.

The method of direct calorimetry already described, has been applied only to animals for the determination of the total heat-loss in fever. Here Wood's experiments are the best which we possess. Leyden and Liebermeister have furnished calorimetric data which, although unsatisfactory in many respects, indicate the general direction of febrile heat-loss in human beings. All of these experiments show that more heat is dissipated in fever than under like conditions in health. The fluctuations of heat-loss during a febrile paroxysm are so great that the statement of an average for the entire period has little significance. Such an average, according to Wood's results on fevered dogs, would fall between twenty to thirty per cent. excess of heat-loss as compared with the loss in health under like conditions of food. The dissipation of heat in fever, however, may be at times more than double the normal amount, and again may sink below the normal. We have not sufficiently accurate estimates either of the total amount of heat produced or of that dissipated during a febrile attack to enable us to strike a balance between the two. Some persons have been so impressed with the large amount of heat-loss during certain periods of fever that they have concluded that there must be far greater excess of heat-production than previous investigations have shown to be probable. They suggest that there are sources of febrile heat of which at present we have no idea. Such conclusions seem to me quite unwarranted when we consider the behavior of heat-loss not for a limited time, but throughout the different stages of a paroxysm of fever. We have already seen that we obtain no satisfactory conception of febrile production of heat unless we follow it during the stages of fever, and this is no less true of heat-dissipation. The observation of the condition of the skin as regards temperature and moisture must in all ages have afforded an insight into the general behavior of heat-dissipation during the different periods of fever. It does not require any instruments of precision to make plain the fact that a cold, dry skin, such as we observe during a febrile chill, liberates less heat than normal, or that a hot, moist skin, such as we are likely to find at the defervescence, loses more heat than normal. Not quite so transparent is the direction of heat-loss during the hot stage or acme of a febrile paroxysm, or fastigium, of a continued fever. Here the skin usually appears hot and dry. The ordinary impression that more heat than normal is dissipated during this stage is supported by calorimetric experiments. There can be no doubt that the elevation of the cutaneous temperature which we observe in the hot stage of fever causes an increase in the amount of heat lost by radiation and conduction. Similar elevations of cutaneous temperature in health, such as those caused by muscular exercise, are accompanied by increased moisture of the surface. Not only is visible perspiration usually absent during the hot stage of fever, but the invisible perspiration is, as a rule, relatively, although not absolutely diminished, as Leyden has shown. The dryness of the skin, therefore, is a factor which, in the hot stage of a fever, tends to less-

sen heat-dissipation. Clinical observation, however, shows that fevers differ markedly from each other as regards perspiration during the hot stage, the skin being sometimes bathed in perspiration, without any depression of temperature. It would undoubtedly be of great interest to possess trustworthy data as to the exact loss of water from the surface of the body in different fevers, and at different stages of fever. We cannot place much reliance upon the indications afforded by Weyrich's hygrometer, which has been repeatedly used for this purpose. More is to be expected from the method employed by Peiper¹⁰ in studying insensible perspiration under physiological conditions.

The general impressions regarding febrile loss of heat derived from clinical observations are supported by calorimetric experiments. The dissipation of heat is least during the initial stage of fever, and greatest during the period of defervescence. During the hot stage or fastigium, heat-dissipation exceeds the normal, but usually, on account of the dryness of the skin, not so much as one might infer simply from the impression of heat received by the hand when placed upon the skin.

During the initial period the loss of heat, although on the average less than in the following stages, is usually greater than normal. If, however, the rise of temperature be rapid, the heat-loss falls below the normal amount. As there is now increased production of heat, there is evidently a glaring disproportion between the two factors, heat-production and heat-loss, and under these circumstances the febrile attack is likely to be ushered in by a chill. During the febrile chill, all the efforts of nature combine to produce in the shortest time the greatest possible elevation of temperature. Not only is heat-loss reduced to a minimum, but heat-production is excited to the utmost.

During the period of defervescence, on the other hand, the relation between heat-loss and heat-production is reversed. This is, of course, most apparent when the fever terminates by crisis, with rapid fall of temperature. Then the loss of heat is excessive, being sometimes three-fold that in the normal state, and heat-production is relatively and often absolutely diminished.

It is of importance to remember that there are continual and irregular fluctuations in the dissipation of heat during the different stages of fever. These fluctuations bear no definite relation either to the momentary production of heat or to the height of the internal temperature. We deal in ordinary life so much more with units of temperature than with units of heat, that it is difficult for us to keep constantly in mind the fact that no inference can be drawn as to the height of the internal temperature from the knowledge of the momentary heat-production and heat-loss. If the heat-loss fall behind heat-production, the temperature of the body rises, and it can remain at this elevated point with either diminished or increased heat-production so long as the heat-loss equal heat-production.

No correct conception of the condition of the heat-regulating mechanism in fever can be obtained without taking into consideration these irregular variations in the discharge of heat, and it is a merit of Senator and his pupils to have emphasized particularly this point. These variations are made apparent not only by calori-

¹⁰ Peiper. *Zelltschrf. f. Klin. Med.* Bd. 12.

metric measurements and direct observation, but also by the studies which have been made of the cutaneous temperature in comparison with the internal temperature in fever. Hankel's law, that the difference between the temperature in the axilla and that of the surface of the body in the febrile condition is less than in the normal condition, manifestly does not hold for the chill, in which it has been proven that the superficial temperature falls, while the internal temperature rises. Jacobson, Wegscheider, and Schülein¹¹ find that there constantly occurs in the course of most fevers changes of the superficial temperature which stand in no relation whatever to alterations of the internal temperature. Schülein thinks that he has discovered some facts in this regard which are available in diagnosis. However this may be, these observations indicate that contraction and dilatation of the cutaneous vessels are constantly occurring, and without any regularity in fever. These irregular variations in the calibre of the bloodvessels are also apparent to the eye in the vessels of the rabbit's ear during fever. When it is considered, furthermore, that these irregularities of cutaneous circulation vary decidedly in different situations, no further proof is needed that the mechanism which regulates the discharge of heat from the surface of the body is profoundly disturbed in fever.

These alterations in cutaneous circulation are such striking phenomena that it is, perhaps, not surprising that two great medical authorities should have based upon them exclusively theories of fever, Traube assuming excitation, and Marey paralysis of vaso-motor nerves as the primal element in fever. We need not discuss these theories, now generally abandoned in their exclusive form. From what has been said concerning the loss of heat in fever, it is evident that we cannot explain febrile rise of temperature solely by the behavior of heat-dissipation any more than we can explain it solely on the basis of increased heat-production. In rejecting Traube's theory that fever is the result solely of retention of heat, we must still recognize the fact that decrease in the dissipation of heat, at times absolute, at other periods relative, is a factor of the utmost importance in the febrile process.

From whatever point of view we consider the question, we cannot avoid the conclusion that it is the mechanism which controls the relation of heat-production to heat-loss which is primarily disturbed in fever.

Heat-production is increased in fever, but if the regulating mechanism were normal, then the discharge of heat would be proportionately increased, and the temperature would not be materially affected. Nor would the force of this argument be changed if febrile thermogenesis were twice as energetic as we suppose it to be.

The loss of heat is increased in fever, so that on this ground alone we should be obliged to assume increased heat-production. But even if it were proven that heat-dissipation is diminished, as has been recently claimed again by Rosenthal,¹² and that fever is the result of heat-retention alone, it would still be necessary to admit that the regulating mechanism is at fault, for Pflüger has demonstrated that when this is normal, changes in the temperature of the skin are attended by such changes in heat-production that the

internal temperature remains within wide limits unaltered.

I repeat then that the conclusion is forced upon us, that the fever-producing agents must act either directly or indirectly upon the mechanism regulating the harmonious relation of heat-loss to heat-production. That the heat-regulating mechanism, although profoundly disturbed, is not entirely paralyzed in fever, is proven by the effect of heat and cold upon fevered individuals. Although Colasanti believed that his fevered guinea-pig had lost all power of heat-regulation under varying external temperatures, a similar conclusion has not been reached by others who have investigated this question. We can best describe the condition of heat-regulation in fever as unstable or ataxic. External cold stimulates to some extent the heat-production of an individual in fever, but by no means as much as it does in health. A person in fever is not able to retain his bodily temperature under the influence of heat and cold, to the same degree that he can under normal conditions. Liebermeister, as is well-known, held that heat-regulation in fever, is simply adjusted for a higher point, although he admits not perfectly adjusted. Experience shows that this so-called adjustment is so unstable that it does not seem proper to compare it with that to normal temperatures in health, so that it is not clear what deep meaning lies in Liebermeister's idea.

We cannot imagine the heat-regulating mechanism to be other than a nervous one. Some years ago this was about as far as the theory of the mechanism of fever could be carried. All paths led to this mysterious nervous apparatus, and beyond this nearly all was speculation. As has been said, we stood before imposing processes veiled in the deepest obscurity. Since then the veil has been lifted here and there and we have caught glimpses of the nature of these processes. I refer particularly to the results of researches which have brought to light a more immediate and direct dependence upon nerve-energy, than had been supposed, of chemical processes concerned in the disintegration and construction of tissue, and therefore in the production of heat.

With one side of the nervous mechanism concerned in temperature-regulation, the classical investigations of Claude Bernard have made us tolerably familiar. This is the vaso-motor nervous apparatus presiding over the circulation of blood in the superficial parts of the body, and thereby controlling in great measure the discharge of heat. That the important part taken by the perspiration in the dissipation of heat is likewise under nervous influence, has been demonstrated by Luchsinger. The facts concerning this side of the regulation of heat are too well-known to require elucidation on this occasion.

Heat-regulation, however, is effected not only by variations in the elimination of heat, but also by changes in the production of heat. Familiar as the fact is it can never cease to arouse our admiration that the temperature of the body remains the same in cold and in warm atmospheres. Man has become so dependent upon clothing that in the naked condition his capacity of preserving his normal temperature in a cold environment is much less than that of most animals. Pflüger has demonstrated that the heat-regulation under varying external temperatures is accomplished by changes both in heat-production and in heat-loss, so that in a cold atmosphere more heat is

¹¹ Jacobson, Virchow's Archiv, Bd. 65. Schülein, Ibid., Bd. 66. Wegscheider, Ibid., Bd. 69.

¹² Rosenthal, Deutsche Med. Wochenschrift, 1898.

produced, and in a warm atmosphere less heat, provided the external temperature is not so high or so low as to make it physically impossible to preserve the body temperature. It is evident that this is the most rational and economical method of retaining the internal temperature of the body. To regulate the body temperature simply by variations in the discharge of heat, as was formerly supposed to be the method, would be, as has been said, like regulating the temperature of our rooms summer and winter by opening and shutting the windows, without controlling the source of heat.

A heat-producing or thermogenic apparatus, therefore, is no less a part of the heat-regulating mechanism than is the heat-discharging or thermolytic apparatus, to use the terms employed by Foster. As the thermogenic apparatus is less generally understood, it is not permissible to dismiss its physiology in this connection so briefly as I have the thermolytic, although our knowledge of the former is very imperfect.

I can assume that the convincing reasons are known to you which have led physiologists to conclude that most of the animal heat is produced in the muscles and the glands, and that the muscles have the larger share in this function. It is also well-known that stimulation of secretory and motor nerves cause not only visible physical alterations in the glands and muscles, but also production of heat. This sort of dependence of heat-production upon innervation has been long admitted. It may, however, not be so generally known that there are reasons to believe that nervous impulses control chemical changes which result in the production of heat independently of visible physical alterations of the tissues; in other words, that heat-production or thermogenesis is at least in considerable part under the immediate and direct control of the nervous system. The idea is not a new one and was advocated especially by Claude Bernard. Recent discoveries, however, have given it unexpected support.

This subject of the relation of innervation to thermogenesis is most pertinent to the pathology of fever, but it is essentially a physiological one and as I wish to confine to a single lecture what I have to say concerning the theory of fever, it is impossible for me to do more than summarize the most essential points belonging here. This I can do more readily as Dr. McAlister¹³ in his admirable Gultonian Lectures on the Nature of Fever, which were delivered last year, has clearly and forcibly presented the main facts.

The larger part of these facts relates to the chemical changes and heat-production of muscles under varying conditions.

That a larger part of the chemical changes in a muscle in the condition which we call repose is under the influence of the nervous system is made apparent by the great diminution in its consumption of oxygen and formation of carbonic acid which follows the separation of the muscles from all connection with the central nervous system. This is conclusively shown by the experiments of Bernard, Pflüger, von Frey and others. It is of course possible and it has generally been supposed that under these circumstances it is simply the withdrawal of motor impulses which lowers the heat-producing energy of the muscle. Far more suggestive as regards the point under considera-

tion are the results of investigations which have been carried on in Ludwig's Laboratory by Meade Smith, MacAlister and Lukjanow. These experimenters have shown that heat-production and contraction are in a measure independent properties of the muscle. By various influences the thermogenic property may be so impaired that a stimulus causes contraction with scarcely any development of heat. The laws governing the restoration and the fatigue of the thermogenic function differ from those controlling the mechanical function. These researches, upon which I here only touch, have made it extremely probable that there are in the muscle chemical processes resulting mainly in the production of heat and chemical processes causing mainly contraction, and that these processes, although co-ordinate, are not identical. A new light is shed upon the meaning of the term chemical tonus of muscle, which has for some time been used by some physiologists. Great caution is properly exercised by Ludwig and his pupils in the interpretation of these interesting results. They do not infer from them necessarily the existence of so-called thermic or calorific nerves. They suggest that it is possible to explain the phenomena upon the supposition that there are in the muscles two kinds of material, thermogenic and contractile, and the nervous impulses acting upon these may pass through the same set of nerves. Proof of the existence in connection with muscles of thermic, in distinction from motor nerves would be afforded if we could succeed after paralysis of the motor nerves in exciting by nerve-stimulation the thermogenic function of the muscle. We possess in curare a drug which paralyzes the terminations of the motor nerves. Meade Smith attempted by its aid to determine whether possible thermic nerves may be differentiated from motor, but he reached no positive conclusion on this point. There are, however, on record some observations which suggest the possibility that in moderate doses curare may leave intact thermic nerves after the suspension of the function of motor nerves. When an animal is profoundly under the influence of curare the internal temperature falls and the processes of oxidation are greatly reduced. The animal is no longer able to resist the changes of external temperature, its own temperature rising and falling like that of a cold-blooded animal when exposed to heat or cold. This effect of curare poisoning is another proof of the dependence of heat-production upon nervous influences. Claude Bernard in his early researches on the action of curare noted elevation of temperature soon after its administration. Recently, U. Mosso¹⁴ claims that an animal may be placed so far under the influences of curare as to paralyze completely the voluntary muscles and the internal temperature either remain normal or rise. He infers that these moderate doses of curare although sufficient to paralyze the motor nerves must have left intact the thermic nerves. That rise of internal temperature is not due to retention of heat he thinks is evident from the normal or elevated temperature of the skin. Mosso is strengthened still further in his conclusion as to the existence of thermic nerves by finding, that after complete paralysis of the motor nerves by curare, injections of strychnine cause an elevation of rectal temperature which may amount to three degrees Centigrade. Under these circumstances strychnine produces no spasms or other visible mechanical effect upon the muscles.

¹³ McAlister. *The Lancet*, 1887, Vol. I.

¹⁴ Mosso. *Virchow's Archiv.*, Bd. 106.

Mosso brings forward a number of other experiments (decidedly open to criticism) intended to demonstrate the existence of nerves directly controlling heat-production, but those which I have mentioned are by far the most striking. It seems to me that the natural interpretation of these experiments is in favor of the view that there are nerves controlling heat-production in the muscle distinct from motor nerves. Far more conclusive as to this point than thermometric observations would be calorimetric experiments determining the heat-production of animals under varying doses of cure.

This whole line of experimentation directed toward the differentiation of the mechanical and the chemical functions of muscle is certainly most suggestive, but so long as the interpretation of the results is not perfectly clear we should be very guarded in drawing far-reaching conclusions. I cannot refrain, however, from pointing out that, as mentioned by MacAlister, all of these thermogenic phenomena may be found eventually to depend upon nerves whose chief function on the one hand is the disintegration, the katabolism of tissue, and on the other hand the restoration, the anabolism of tissue. From the study of the electrical changes which stimulation of the pneumogastric nerve produces in the heart-muscle, Gaskell concludes that this nerve puts the heart in a condition of relative rest, during which the energy of the muscle is increased. During this period there is reason to believe that the material of the muscle, which when disintegrated gives rise to heat and mechanical work, is in the process of restoration. Hence Gaskell speaks of the pneumogastric or inhibitory nerve of the heart as anabolic; that is, it directs the restorative, formative, anabolic processes in the muscle. On the other hand, the accelerator nerve of the heart induces the opposite electrical changes in the heart-muscle. Gaskell describes this nerve as katabolic; that is, its stimulation causes disintegration of the muscle-materials and liberates energy in the form of heat and of mechanical work. If it be found that similar inhibitory and accelerator nerves preside over the chemical changes in the voluntary muscles and other tissues of the body, then Gaskell's induction as to the existence of anabolic and katabolic nerves must be regarded as one of the most important and profound in modern physiology. Thermo-excitatory nerves we should then rank as katabolic, thermo-inhibitory as anabolic.

These investigations tending to demonstrate the independent existence of thermogenic properties in the muscles and possibly of nerves directly controlling thermogenesis, have prepared us for the consideration of the relation of the central nervous system to the heat-producing properties of the body. Here you will willingly permit me to confine my remarks to the more essential and best established facts, without entering into a full discussion of one of the most perplexing subjects in the physiology of the nervous system.

The clinical basis of the doctrine that lesions of the central nervous system influence directly the temperature of the body, was laid by Sir Benjamin Brodie, who reported the well-known case of fracture of the cervical vertebrae and injury of the spinal cord, followed within a few hours by a rise of temperature to 111° F., measured between the scrotum and the thigh. Since then, many similar instances have been reported. It is well to remember in framing theories

on the basis of these cases that there are also on record not a few instances in which apparently similar injuries of the same parts of the spinal cord have been followed by equally striking falls of temperature.

The experimental basis for the acceptance of an influence of the nervous system on temperature, was laid by Bernard in his celebrated experiments on the effects of division of the sympathetic nerve in the neck. Bernard interpreted the increased temperature of the ear following this operation as referable not only to the larger amount of blood in the part, but also to increased tissue metamorphosis and consequent heightened heat-production. The latter part of this interpretation is not generally accepted. It may be said here that the common idea that an organ or tissue simply because it receives a larger supply of blood indulges in more active metabolism is opposed by the investigations of Pflüger, who finds that the amount of oxygen taken up by the cells depends in a far higher degree upon the state of their innervation at the time than it does upon the supply of oxygen. The demand of the tissues for oxygen is not increased simply because the supply is greater. The arguments upon which Pflüger bases this line of reasoning, although not without opposition, would dispose of the idea that when any considerable increase of heat-production in the muscles occurs, this can be explained simply by vaso-motor changes. I mention this here because the opinion has been advanced that a large part of the increased production of heat in fever, and after certain injuries to the nervous system, is referable simply to vaso-motor changes in the muscles.

In 1866, Tscheschichin¹⁶ published experiments which he interpreted as indicating the existence in the brain of centres which, when irritated, moderate the production of heat, and which he called heat-moderating or heat-inhibitory centres, and in the spinal cord of centres which, when stimulated, excite the production of heat—heat-excitatory centres. These conclusions were not justified by the experiments, but they have been widely accepted.

I may say here that in this connection I use the term heat-centres as a convenient and generally adopted one. There is a proper reaction against the prevailing misuse of the word centre for all sorts of little understood localization of nervous functions. It would undoubtedly be more accurate to use some such expression as thermically active region, instead of heat-centre.

It is not easy to reconcile the clinical fact that in human beings lesions of the spinal cord may be followed at once, or in a very short time, by extraordinary elevations of temperature, with the results of experiments on animals. That the rise of temperature in human beings is not due to inflammatory fever, is apparent from the rapidity with which it follows the injury. It cannot be explained by vaso-motor lesions, for the paralysis of the vaso-motor nerves accelerates the discharge of heat from the surface of the body. The high temperature can be explained on Tscheschichin's assumption. The lesion either directly stimulates the spinal thermogenic centres, or removes the influence of the thermo-inhibitory centres. These clinical observations are the strongest support which has been found for the belief in the existence of centres in the spinal cord which accelerate heat-production. Section of the cervical part of the spinal cord

¹⁶ Tscheschichin. Reichert u. du Bois, Reymond's Archiv., 1866.

in a dog or a rabbit is, under ordinary conditions, always followed by a rapid fall of the internal temperature and diminished oxidation. These varying results in man and in animals have been explained by supposing that after section of the cervical cord, on the one hand, the discharge of heat is increased by dilatation of the superficial bloodvessels in consequence of vaso-motor paralysis; and, on the other hand, the production of heat is increased by withdrawal of thermo-inhibitory cerebral impulses. If, as ordinarily happens in dogs and smaller animals, the first factor predominates, then, in consequence of sinking of the internal temperature, the heat-producing processes are so reduced that the influence of the second factor is not manifest. The attempt has been made to test this explanation by placing the animal, after section of the cord, in a warm atmosphere. If thereby the heat-discharge be reduced to a minimum, it is found that the internal temperature of the animal with severed cord rises more rapidly than that of a normal one under the same external conditions. Here thermometric observations are not conclusive as to the point to be tested, for the more rapid rise can be explained simply by failure of the heat-regulating mechanism. Wood's calorimetric experiments seem to show that there is greater heat-production under these circumstances in the animal with a cut cord. These experiments admit of various interpretations, but if they be regarded as establishing the assumption from which we started, then it is evident that in man and in large animals the increased heat-production after injury of the cord would not be so readily overcome by the increased discharge of heat from the surface, for, in proportion to its volume, a large animal has less surface than a small one. The interplay, therefore, of these opposing tendencies might cause different results, according to the size of the animal.

Tscheschichin found that a transverse section made at the junction of the pons and medulla oblongata is followed in a short time by rise of internal temperature. As the superficial temperature is also elevated, he concludes that there is no retention of heat; moreover, the section is made above the dominant vaso-motor centre. Wood has shown by means of the calorimeter that after this operation there is actual increase in the production of heat. He, as well as Tscheschichin, interpret the experiment as indicating thermo-inhibitory centres above the lower border of the pons. Bruck and Günter¹⁶ repeated and modified these experiments under Heidenhain's direction. Out of seven cases in which they separated the pons from the medulla, they observed only in two rise of temperature; of eleven cases in which they punctured the pons with a needle, in five they noted increased temperature. Heidenhain thinks these experiments indicate heat-exciting, rather than heat-moderating centres, and it must be admitted that the evidence is not conclusive in support of either view.

By far the most interesting and conclusive experiments showing the influence of the central nervous system on thermogenesis are those of Isaac Ott, followed by Richet, Aronsohn and Sachs, Baginsky and Girard.¹⁷ The observations of Ott, Richet, Aronsohn,

and Sachs were made independently and at about the same time, but Ott was the pioneer. The experiments of Aronsohn and Sachs are reported with especial fullness and detail. These investigators find that if the skull of a rabbit be trephined at the junction of the coronal and sagittal suture, and a needle be passed vertically down so as to puncture the anterior part of the caudate nucleus near its median convexity, there follows a rise of body-temperature which may amount to three degrees or more, and which may persist for two or three days. The rapidity and the duration of this elevation of temperature varies somewhat with the depth of the puncture, parts immediately beneath the caudate nucleus being also thermically active. Puncture of the overlying cortex or medullary substance has no such effect upon temperature. With the exception of some increase in the frequency of the respiration and of the pulse, the animal, after puncture of the anterior median part of the caudate nucleus, presents no abnormal symptoms other than the rise of temperature. I have several times repeated this experiment, and always with the result described. That the pyrexia induced by puncture of the caudate nucleus is not due to vaso-motor changes causing retention of heat, is proven by Richet's and Ott's calorimetric experiments, and by the determination by Aronsohn and Sachs that the consumption of oxygen and the elimination of carbonic acid and urinary nitrogen are increased. Aronsohn and Sachs and Girard find that electrical stimulation of the anterior median part of the caudate nucleus causes the same thermic phenomena as the puncture, and they, therefore, conclude that this region contains a thermo-excitator heat-centre. This is the natural interpretation of their experiment, although Baginsky and Ott regard the centre as thermo-inhibitory on grounds which cannot be considered convincing.

Ott claims that there are four cerebral heat-centres, one about the corpus striatum, the second in the caudate nucleus, the third in the anterior inner end of the optic thalamus, and the fourth near the median line between the optic thalamus and the corpus striatum. The greatest rise of temperature he found after injury of the thalamic centre.

No adequate demonstration has been afforded of any influence of the cerebral hemispheres upon thermogenesis. Corin and van Beneden¹⁸ find that pigeons after removal of their cerebral hemispheres exhibit no change of temperature, no failure of the heat-regulating mechanism, and no alteration in the excretion of carbonic acid.

I have endeavored to present to you the main physiological facts bearing upon the relation of the nervous system to thermogenesis. It must be admitted that we are left to surmises as to the interpretation of many of the facts, and particularly as to their connection with each other. But certain important points come out clearly. We have found evidence of the existence in the body of chemical processes, resulting chiefly in the production of heat-energy. We have learned that these processes are under the direct control of the nervous system, and possibly of nerves distinct from those now recognized as motor or secretory. We have seen that there are regions in the central nervous system which are doubtless in some way connected with these nerves, and through them

¹⁶ Bruck and Günter. *Pflüger's Archiv.*, Bd. III.

¹⁸ Corin and van Beneden. *Arch. de Biologie*, 1887.

control the chemical processes resulting in the production of heat.

The bearing of these facts upon the theory of fever is evident. The study of heat-production and of heat-loss in fever has led us, by arguments which need not be repeated, to the conclusion that the pyrogenic agent must, in some way, act upon the heat-regulating mechanism. The study of this mechanism, more particularly of its thermogenic side, affords some insight into the manner in which the fever-producing agent may affect the regulation of heat. The main difficulty in the neurotic theory of fever has been to understand how, by any action of the fever-producing agent directly upon the nervous system, the chemical processes leading to heat-production could be stimulated. I have dwelt thus at length upon the innervation of thermogenesis to show that this difficulty has been overcome. To some it seems more reasonable to suppose that the pyrogenic agent circulating in the blood acts directly upon the tissues, altering and stimulating their chemical changes. This is the hæmic theory which, in some form, has always stood over against the neurotic theory of fever. Although it may at first glance appear simpler, the hæmic theory is really the more complicated, for it has already been set forth that we cannot explain fever simply by increased heat-production, so that even if the primary effect of the fever agent were upon the heat-producing processes, there must be a secondary influence upon the nervous system, for heat-dissipation is no less disturbed than heat-production.

If an animal be thoroughly curarized, so that no impulses from the nervous centres can reach the muscles, the great heat-producers, then it is found to be impossible to produce febrile elevation of temperature by the injection of pyrogenic agents. This fact, first demonstrated by Zuntz, is justly held to weigh heavily in favor of the neurotic theory of fever.

Contrary to the results of Murri,¹⁹ I have not been able to induce rise of temperature, or check its fall by the injection of pyrogenic agents into the jugular veins of dogs whose spinal cords have been cut in the lower cervical region. In these experiments I have employed various pyrogenic agents, and especially pepsin and papoid. One specimen of the latter which I used possessed very striking pyrogenic properties.

The pyrexia produced by puncture of the caudate nucleus in the manner already described possesses all of the essential properties of fever, regarded as abnormal elevation of temperature. In this experimental condition there are increased production of heat, increased dissipation of heat, excessive elimination of urea and of carbonic acid, and excessive absorption of oxygen. The breathing and the pulse are increased in frequency. The elevation of temperature (usually after a brief fall) begins within half an hour after the puncture, attains a febrile height, and persists sometimes for days. As no observations exist as to the heat-regulation of these animals, I have made experiments on rabbits after puncture of the caudate nucleus by placing them in a cold environment, and in a box heated to various temperatures, and I find that their power of temperature regulation is less than that of normal animals. These animals, in a word, present all of the essential symptoms of fever, and I do not know why we should not call the

condition fever. If so, we must admit that injury to a circumscribed, definite region of the brain is capable of causing fever. This experiment, therefore, is of the greatest importance in support of the neurotic doctrine of fever. It indicates, of course, that we may have fever of purely nervous origin without any pyrogenic agent in the blood. This experimental evidence is supported by the clinical cases collected by White in Guy's Hospital reports (1884). It is to be hoped that by careful thermometric study of focal brain and cord lesions a more accurate idea may be reached than is now possible of the topography of the thermically active regions in the central nervous system of man.

Admitting the dependence of fever upon the nervous system, I do not regard as particularly profitable with our present knowledge the discussion as to whether febrile thermogenesis is excited by the withdrawal of thermo-inhibitory impulses, or by the stimulation of thermo-excitatory nerves or nerve-centres. If we regard, and there are forcible arguments for doing so, the heat-inhibitory nerves as anabolic, and the heat-exciting nerves as katabolic, then, inasmuch as the formative, or anabolic processes are manifestly in abeyance in fever, we can reasonably infer that the function of the heat-inhibitory nerves is impaired. The phenomena of the febrile chill, in which both the contractile and the thermogenic properties of muscle are stimulated, speak strongly in favor of direct irritation of the heat-exciting nerves in fever. We might infer, therefore, that both sets of nerves are affected.

But my aim in this lecture has been not so much to construct a theory of fever, a theory which, although it may be useful, must necessarily be largely speculative if it be coherent and rounded, but to bring before you the main facts concerning heat-production, heat-loss and heat-regulation in fever, and to point out the physiological basis on which their solution is to be expected.

Original Articles.

ON THE SELECTION OF A CLIMATE FOR PATIENTS WITH PULMONARY TUBERCULOSIS.¹

BY FREDERICK L. KNIGHT, M.D.,
Assistant Professor Harvard Medical School.

PREFACE.

I HAVE often been asked to give the profession some brief practical hints on the choice of a climate for tuberculous patients. I am induced to comply with this request, although there is still a great diversity of opinion among those conversant with the subject, because there seems to be so little attempt even at any guidance of patients in this important matter.

I shall make no endeavor to review the constituents of climate, or to philosophize on their mode of action. I shall briefly present typical cases of pulmonary tuberculosis of different kinds, and point out how I should determine whether the patient should be sent away from home at all, and if sent, to what region of our own country.

I wish it to be distinctly understood that I am giving simply my own convictions on this important subject, based upon twenty years experience, and that I

¹Read before the Boston Society for Medical Observation, March 5, 1888.

¹⁹ Murri. *Teoria della Febbre*. Fermo, 1874.

do not claim that the principles which guide me are by any means universally accepted by climatologists. If I designate any special places for residence, it is because they offer some accommodations and are well known, but of course it will be understood that there are scores of similarly situated regions which would answer just as well as far as climatic conditions are concerned.

SHALL PATIENTS THREATENED WITH, OR ALREADY HAVING PULMONARY TUBERCULOSIS, BE ADVISED TO CHANGE CLIMATE?

This is a serious question, not to be settled offhand, and one entitled to much more consideration before being answered, than is usually accorded it. Not only is serious inconvenience and great expense often unnecessarily caused a patient and his family by hasty advice in this regard, but his condition is not infrequently made worse by it. This may happen in cases in which rest at home would have been better than any change, or in which the destination has been improperly specified, or perhaps not specified at all. In every case the condition of the individual patient must be carefully considered, whether any climatic change could possibly improve it, and, if so, what kind of a change would be most likely to effect it.

Other considerations, however, besides the disease of the patient, have an important bearing upon the question of change. Can the patient afford it? The physician should satisfy himself on this point, if possible, before mentioning its probable benefit to the patient himself, for it is cruel to recommend what is beyond the resources of a patient, and oftentimes more sacrifice than should be, is made to carry out ill-considered advice of the physician.

In reckoning the expense of change it must be considered: (1) Whether it is to be temporary or permanent; (2) Whether the patient can lead an idle life, or must engage at once in some remunerative occupation; or, having remained idle for a certain time, there would be a good prospect of his resuming some employment.

In answering the first question it must be borne in mind that, as a rule, if an arrest of the disease is sought, a climate should be selected, if possible, in which the patient can remain throughout the year; if palliation only is sought, then a mild climate might be chosen in winter, which would be utterly unbearable in the summer.

It is not always wise to tell a patient on leaving home that his stay is to be indefinite, but when once he is away it is not difficult to prolong his stay; in fact, if the invalid improves he is very apt to become attached to the spot where the improvement occurs. In answering the second question, it should be remembered that while an absolutely idle and indolent life is necessary for some patients, at least during the time of serious constitutional disturbances, there are many patients, free from such disturbances, who are better for occupation, provided it keeps them a good deal in the open air. Indoor life diminishes enormously the chances of improvement from change of climate.

For many years the one idea of the practitioner was to get his pulmonary patients into a mild climate, one soothing to cough, and this notwithstanding the fact that consumption was rife among the natives of the land to which they were sent. In more recent years, it having been found that elevated regions show a re-

markable exemption from the disease among their natives, it is becoming too much the custom to send all consumptives thither, without regard to their condition, ignoring the fact that the climatic conditions best suited to pulmonary disease, vary with the nature and condition of each case, and that those required for prophylaxis may be very different from those demanded for the treatment of advanced disease.

Patients with pulmonary tuberculosis present a great variety of conditions, of which the following are the principal types:

(1) Those presenting the earliest physical signs of tuberculosis of the apex; who have as yet shown little, if any, general disturbance from the disease, and who complain only of morning cough and expectoration. Threatened cases of hereditary disease, in which there are as yet no morbid physical signs, and not much constitutional disturbance, may usually be considered with this class.

(2) Patients with more advanced disease, showing some consolidation, but no excavation, nor any serious constitutional disturbance.

(3) Hemorrhagic cases, that is, patients in whom pulmonary hemorrhage has been perhaps the earliest, and a frequently recurring symptom, but in whom there is as yet no marked febrile reaction, nor much physical evidence of disease.

(4) Patients with advanced disease, those with cavities or severe hectic symptoms.

(5) Patients in an acute condition.

(6) Cases of so-called fibroid or interstitial pneumonia.

(7) Patients recovering from acute pleurisy or pneumonia, in whom the eruption of tubercle is dreaded.

(8) Patients in whom the tubercular process has seriously invaded the larynx.

(9) Those with complications of other diseases, heart, renal, intestinal, rheumatic, etc.

The first object to be secured is an out-door life in a pure air. This undoubtedly has a beneficial local effect, but the chief good comes through the general improvement in nutrition produced by an open-air life, and this is much increased by the ability of the patient to take exercise, and reaches its maximum benefit when he can lead an active, out-door life at considerable elevation (4,000 to 8,000 feet above the sea-level).

It will be seen as we go over the different classes of cases with reference to their individual indications that some of them are not suited to the severity of the mountain-air treatment. Changes of temperature in the mountains are often very great and very sudden, and though equality is not of so much importance as was formerly supposed, yet a certain amount of vigor is necessary to react properly to them. There seems little doubt that in suitable cases the improvement in nutritive activity is much more marked in mountainous regions than on the plains. There are probably several causes for this. (1) In a properly selected place, the air is rarified, causing increased respiratory activity. (2) The air is very dry and very pure. (3) The number of clear days when the invalid can be outdoors, is vastly in excess of those on the plains.

Certain modifying influences which pertain to the individual, have always to be borne in mind. It can be easily understood that a more rigorous climate, one involving the necessity of more active exercise can be recommended to men than to women. The difficulty

of securing sufficient out-door life for women, even in a mild climate, constitutes one of the chief factors in the relatively bad prognosis in tuberculosis in women as compared with men. Patients with much bronchial irritability often do less well in a very high altitude than in a lower one, and the same is sometimes true of a decidedly neurotic temperament. Age, also, must be considered in reference to possible removal to high altitudes. A very high elevation should not, as a rule, be recommended to a patient over fifty years of age.

Wherever the patient goes he should, if possible, consult some good physician of the region, who will lay out for him a plan of life. Many patients make themselves sick, and even destroy their chance of recovery by neglecting to consult a local authority for this purpose.

We will now consider the indications furnished by the types of the disease as before classified.

(1) Those presenting the earliest physical signs of chronic tuberculosis of the apex, who have as yet shown little, if any, general disturbance from the disease, and who complain only of morning cough and expectoration.

It is this class of cases especially which shows the effect of improved ideas of treatment. The change from the old plan of enforced invalidism to an active out-door life has brought about many cases of arrest in this stage of the disease. It is, perhaps, not saying too much to say that the prognosis has been changed as regards this class of cases from very bad to very good.

While I have had such patients do well in different climates, some of them without leaving home, the results have averaged far better, in my experience, in those who have sought mountain climate than in those who have pursued any other course. The region which I have found best for this kind of treatment is the eastern slope of the Rocky Mountains, in the States of Colorado and New Mexico, where the altitude ranges from 4,000 feet to 8,000 feet.

The question will naturally be asked whether the patient should go at once from the sea-board to such a high elevation, or make a number of stops on his way out, in order to become accustomed to the diminished pressure. I have never known any ill effect in patients of this class from making the change at once; but it is especially necessary that they should consult a good local medical adviser at once, that they may be guided from the beginning particularly in regard to the kind and amount of physical exercise which they should take.

(2) Patients with more advanced disease, showing some consolidation, but no excavation, nor any serious constitutional disturbance.

The mountain climate is suited to many of this class also, and it is fortunate if they are in condition to try it, but if considerable area of one lung, or the apices of both, are consolidated, and there is well-marked constitutional disturbance, if the pulse and temperature are both constantly above 100, then it may be well to try some low altitude first. For very low elevations, the dry, rather stimulating air of Aiken and its vicinity, or the pine regions of Southern Georgia, may be recommended for the greater part of the year, the patient going north in the summer. When quiescence in the morbid processes is established a move to the higher altitudes should be made.

(3) Hæmorrhagic cases, that is, patients in whom a

pulmonary hæmorrhage has been perhaps the earliest and a frequently recurring symptom, but in whom there is as yet no marked febrile reaction, nor much physical evidence of disease.

This class seems particularly suited to the high altitude treatment. Contrary to the old idea, these patients appear to be less liable to hæmoptysis in high altitudes than on the plains. I do not remember any patient of this class in whom the tendency seemed increased by the removal to a high altitude, and although such patients are usually advised to make several stops on their journey upward, I doubt if this precaution is often necessary. Of course it will be understood that what is said in this connection does not refer in any way to the hæmoptysis from rupture of a large vessel in a cavity of advanced disease.

(4) Cases of advanced disease, those with cavities or severe hectic symptoms.

Patients of this class had better, as a rule, stay at home; certainly if they are sick enough to be confined to the house. They can usually be made much more comfortable in their own homes than at any health resort, yet I have sometimes advised that such a patient with very constant and harassing cough be sent to the moist climate of Florida, and the relief to the cough has more than compensated for the want of some home comforts. A poor patient, or one without abundant means even, should not be given such advice.

(5) Patients in an acute condition.

These may be quite different in their nature and requirements. We find (a) cases of acute general infiltration. These patients should be kept at home definitely. (b) Cases which begin violently with high fever and marked consolidation of lung, resembling pneumonia. Patients of this class should be kept at home till after the subsidence of the acute symptoms, and then may be removed to some low, dry place; afterward increasing elevations may be carefully tried. (c) Cases of acute exacerbation during the progress of chronic disease. Patients of this class should remain at home during the acute stage, going, perhaps, to some mild, sedative climate during its decline; but as soon as possible after the febrile disturbance is well over, if their condition otherwise warrants it, they should go to an elevated region.

(6) Cases of so-called fibroid or interstitial pneumonia. Special indications in these cases have to be considered. If the patient is young, and the heart is not enlarged, he may be sent to high elevations. If he is over fifty years of age, or if his heart is dilated, or if his cough is very harassing, a lower altitude should be chosen. Southern California offers excellent places for such, with varying elevation and moisture to suit individual symptoms.

(7) Patients recovering from acute pleurisy or pneumonia, in whom the irruption of tubercle is feared. High elevations is the place *par excellence* for these. The increased respiratory and consequent increased nutritive activity are exactly what is wanted to prevent the development of chronic disease.

(8) Patients in whom the tubercular process has seriously invaded the larynx.

Such patients should be recommended mild, and even moist climates, and on no account be sent to high altitudes. Southern California answers the purpose well. The dry air of high altitudes, however much good it may do by stimulating general nutrition, usually proves so great a local irritant to the larynx

that incessant cough ensues, or, if the disease is situated high in the larynx, the swelling and ulceration of the cartilages are aggravated so that severe dysphagia and insufficient nourishment ensue.

(9) Those with complications of other diseases.

In regard to these a good deal of care has to be exercised oftentimes. In case of cardiac affection it may be said that while marked dilatation should prevent a patient's being sent into a high altitude, it is not necessary to exclude every one from such who has a cardiac murmur, or who even is known to have organic valvular disease, with moderate hypertrophy, but such patients should be carefully watched and regulated in their habits, and should not be sent into the very highest altitudes.

In regard to renal disease, while it is admitted by the resident physicians that *acute* nephritis is severe in high altitudes, they do not admit that patients with chronic disease are made worse, but claim rather that they are benefited by a residence there.

Patients with intestinal ulceration are said to do badly in high altitudes, but they do badly everywhere.

In regard to the rheumatic diathesis, it may be said that acute rheumatism is thought to be rather prevalent and severe in high altitudes, and such a tendency might turn the balance in favor of a lower resort. On the other hand the chronic form of rheumatism does not seem to be made worse by elevation.

THIRTY CASES OF LAPAROTOMY.

BY J. W. ELLIOT, M.D.

In Table I there are twenty-two cases, with one death, or four and a half per cent. mortality. Of the entire thirty cases four died; thirteen per cent. mortality. If we exclude the unfinished operations, there are twenty-seven cases, with two deaths, or seven per cent. mortality.

I shall not speak of the technique or manner of operating, as that is practically settled, but shall merely report the cases very briefly. As fatal cases are always instructive they are given more in detail.

The table contains all the laparotomies I have done to date. They are not selected cases, as I have never refused to operate in an unfavorable case where the operation was indicated, but have considered it a matter of duty to give the patient a last chance. Two out of the four deaths here recorded were of patients in almost a dying state at the time of operation. To offset these trying cases four others have been saved by the operation from a similar condition.

In the thirty cases all the wounds which were closed (that is, where no drainage-tube was used) have, with a single exception, healed by first intention, without even a suppurating stitch-hole. There is but one case of hernia at the scar, and that was the result of wearing a drainage-tube for over a year. In closing the wound the whole abdominal wall is included in wire sutures, and the patients are always kept in bed for two weeks.

Beside the ordinary methods of cleanliness and antiseptics, I have abandoned sponges as being a cause of infection, and use in their stead an artificial sponge made of worsted, as already described.¹

There were fourteen hospital patients, with four deaths, and sixteen patients operated on either at home or at a private hospital, without a death.

Under ovariectomy are included both large and small ovarian tumors. Among fifteen cases were four dermoid and three papillomatous cysts. One died. All but one of the others have been heard from, and have remained well. The first five cases have already been reported.²

CASE VI was a dermoid cyst complicated with a complete prolapse of the uterus. At the operation I was able to pucker up the broad ligament and include it in my ligature in such a way as to hold the uterus well up in antiversion. It is now nearly three years, and there has been no return of the prolapse.

CASE VII was a small cyst of the broad ligament. After removal it was found to contain a papillomatous nodule of considerable size. This case suggests the importance of early operations.

CASE X. Two cysts; one with a twisted pedicle. At the operation the bladder was found spread out flat and glued to the under side of the abdominal wall. This was encountered in the incision, and with difficulty avoided. Two ovarian cysts were removed. One a papillomatous cystoma, which had been treated for a fibroid of the uterus by her physician with ergotine injections; and papillomatous excrescences were found protruding through the holes made in the cyst wall by the injecting needle. These papillomatous excrescences had not yet infected the peritoneum, but had caused ascites. This cyst is preserved in the Warren Museum of Harvard University. The other cyst contained blood, and had a twisted and degenerated pedicle. After the operation the temperature rose to 102° on the first day, and continued high; between 102° and 103°. On the fifth day, the patient being considered septic, the wound was re-opened and a quantity of pus found between the omentum and the abdominal wall. On the sixth day, as the patient seemed to be dying of blood-poisoning, transfusion of salt and water was tried with only temporary benefit, and she died on the same day. It was afterwards discovered that by a mistake of the assistant several instruments not properly cleansed were mixed in with the "laparotomy instruments." I have never been able to decide in my own mind whether the septic infection came from the doubtfully clean instruments, or from the twisted and degenerated pedicle.

CASE XI was an obstinate and discouraging case of neurasthenia, sent to me by Dr. J. J. Putnam for local treatment. The uterus was retroverted, and both ovaries were large and tender. After some local treatment and several consultations, Dr. Putnam advised removal of the ovaries. Dr. Homans also advised the operation. The enlarged ovaries proved to be true cystomata. The effect on the neurasthenic condition was excellent, and the patient is now almost perfectly well. The retroversion has never returned.

CASES XIV and XV were suppurating cysts so adherent that their removal was impossible. The cyst walls were, therefore, stitched to the abdominal walls and drained. These cases have been reported in full.³

Out of a large number of diseased fallopian tubes which have come under my care within the last three

THIRTY CASES OF LAPAROTOMY.

TABLE I.—OPERATIONS FOR DISEASES OF PELVIC ORGANS.

A.—Diseases of the Ovary. Ovariectomy.

No.	Date of operation	Age	Married or single	Hosp. or private	Pathological condition found.	Ovaries removed	Drainage	Result	Remarks
1	1884 January	32	M.	H.	Large cystoma deep in broad ligament	Both	No	Recovered
2	March	49	M.	H.	Dermoid Cyst (large)	One	No	Recovered	Well in 1886
3	October	22	S.	H.	Cystoma	One	No	Recovered	Alive in 1888
4	October	24	S.	P. H.	Dermoid Cyst	One	No	Recovered	Well in 1888
5	November	28	M.	H.	Parovarian Cyst	One	No	Recovered	Well in 1887
6	1885 May	38	M.	P. H.	Dermoid Cyst	One	No	Recovered	Well in 1888
7	June	25	S.	H.	Papillomatous Cyst of broad ligament	One	No	Recovered	Well in 1888
8	October	24	M.	H.	Dermoid Cyst L. O. Cystoma R. O.	Both	No	Recovered	Well in 1888. Catamenia have not appeared since operation
9	November	23	S.	P. H.	Small fibroma of ovary	One	No	Recovered	Other ovary removed later by Dr. G.
10	1886 February	40	M.	H.	Papilloma of R. O. hæmatoma with twisted pedicle L. O.	Both	No	Died	Septic Peritonitis
11	April	32	S.	P. H.	Small cystomata of both ovaries	Both	No	Recovered	Well in 1888
12	May	39	M.	P.	Suppurating tubo-ovarian cyst. Cyst broad lig.	One	Yes	Recovered	A very severe operation. Well in 1888
13	1887 January	28	S.	P.	Cystoma both ovaries, cyst broad ligament	Both	Yes	Recovered	Well in 1888. Catamenia irregular since operation

Drainage of Suppurating Ovarian Cysts.

14	1885 April	19	S.	H.	Suppurating Cyst, universally adherent.	One	Yes	Recovered	Sinus closed in about one year. Married and well in 1887
15	April	28	M.	H.	Suppurating papilloma universally adherent	One	Yes	Recovered	Relieved for two years, then another tumor appeared, patient lost sight of

Removal of Ovaries not the Seat of Tumors.

16	1885 May	37	S.	P.	Fibroid tumor of uterus	Both and tubes	No	Recovered	In 1887 menstruation had never returned. Fibroid disappeared
17	1887 October	20	S.	P.	Profound hysteria of long standing	Both and tubes	No	Recovered	Three months later great improvement. No menstruation
18	1888 January	33	S.	P. H.	Chronic ovariitis and peri-ovariitis	One	No	Recovered	Pelvic peritonitis for 10 years before the operation

B.—Diseases of the Fallopian Tubes. Salpingotomy.

19	1885 April	35	S.	P.	Salpingitis	Both Tubes	No	Recovered	A small piece of one ovary left. Menstruation has continued irregularly ever since operation. Patient cured
20	1887 January	27	M.	P. H.	Double Pyosalpinx of large size	Both Tubes	Yes	Recovered	Left tube contained 8 oz. of pus
21	May	26	M.	P. H.	Hydrosalpinx	One	No	Recovered	Cured

C.—Diseases of Uterus. Hysterectomy.

22	1886 November	37	S.	H.	Fibroid of uterus growing rapidly	..	No	Recovered	Extra peritoneal stump. Temperature normal on third day. One year after operation the patient was well and working in a mill
----	---------------	----	----	----	-----------------------------------	----	----	-----------	--

TABLE II.—OPERATIONS FOR DISEASES OF OTHER ABDOMINAL ORGANS.

A.—Evacuation of Pus.

No.	Date of operation	Age	Sex	Hosp. or Private	Pathological condition found	Operation	Drainage.	Result	Remarks
23	1885 June	28	F.	H.	Suppurative peritonitis due to suppurating ovarian cyst	Evacuation of pus and drainage	Yes	Recov.	Patient in a very critical condition at the time of operation
24	1887 November	32	M.	P.	Intra-peritoneal abscess due to perforating appendicitis	Evacuation of pus and drainage	Yes	Recov.	General adhesive peritonitis. Incision parallel to Poupart's ligament

B.—Intestinal Obstruction.

25	1886 May	44	M.	H.	Cancer very high up in rectum	Median incision; bowel stitched to wound and opened	No	Died	Obstruction had existed for a month and the patient was almost in a dying condition
----	-------------	----	----	----	-------------------------------	---	----	------	---

C.—Evacuation of Ascites.

26	1886 April	43	F.	P. H.	General peritoneal cancer	Median incision and permanent drainage	Yes	Recov.	Great relief from drainage. Died later of the disease
27	1887 December	14	F.	P. H.	Tuberculosis of Peritoneum	Thorough evacuation of ascites	No	Recov.	Great relief. Well four months later

5 Cases, 1 Death.

TABLE III.—EXPLORATORY AND UNFINISHED OPERATIONS.

28	1884 April	30	F.	H.	Sarcoma of ovary and pyosalpinx	Exploratory incision	No	Died	Patient in a dying condition; operation done as a forlorn hope
29	1886 May	32	F.	H.	Chronic peritonitis, salpingitis and ovaritis	Attempt to remove ovaries and tubes	No	Died	Operation abandoned on account of adhesions. Death from peritonitis. Autopsy showed that the operation was impossible
30	1887 October	31	F.	P. H.	Fibroid deep in broad ligament	Tumor partially enucleated and blood supply and part of pedicle ligatured	Yes	Recov.	Operation abandoned because the tumor seemed to be on the ureter

3 Cases, 2 Deaths.

years there were four cases where it was necessary to remove the tubes, one case (No. 12) being included in the ovariectomy table on account of complications. All recovered, although the abdominal cavity was contaminated with pus in two cases.

CASE XIX was a double salpingitis complicated with a retroversion of the uterus, which was permanently cured by puckering up the broad ligaments. Menstruation has continued, although the tubes were removed close to the uterus.⁴

CASE XX. The left fallopian tube was as large as a cocoanut, and imbedded in the broad ligament and adhesions. The right was enlarged to the size of a fist so close to the uterus that there was no pedicle. It was necessary, therefore, to amputate it without clamp or ligature, and take up the vessels separately. Pus escaped into the abdominal cavity, and a glass drainage-tube was used. The patient made an excellent recovery, and was up on the fourteenth day.

CASE XXII was a very rapidly-growing fibroid. The uterus was amputated at the internal os. The uterine canal at that point was large enough to admit two fingers. The stump was constricted with a wire ecraseur, and treated extra-peritoneally. The peri-

toneum was stitched to the stump below the wire. Recovery was uninterrupted.

The operations in Table II were all for very formidable diseases, and the mortality is higher than in Table I.

CASE XXIV was a laparotomy done for perforation of the vermiform appendix.⁵

CASE XXV. Intestinal obstruction had existed for a month, and the patient was in a very bad way. There was vomiting, the abdomen was greatly distended, and the pulse was rapid. Nothing could be discovered per rectum. At the operation the seat of obstruction could not be found on account of the enormous distension of the intestines, so a loop of intestine was opened and stitched to the abdominal wound. The intestine failed to unite firmly to the wound (probably on account of the poor general condition of the patient). There was, therefore, leakage of feces into the peritoneal cavity, which caused peritonitis and death on the eighth day. The autopsy showed a cancerous obstruction high up in the rectum.

CASES XXVI and XXVII. Both patients were very large with ascites; in one case due to cancer of the peritoneum, and the other to tuberculosis. Both cases were interesting on account of one point in diagnosis; name-

⁴ E. M. and S. Journal, April 15, 1886.⁵ Reported in full in B. M. and S. Journal, Jan. 19, 1888.

ly, in both, the loins were tympanitic on percussion, while there was dulness over the whole of the rest of the abdomen; and change of position did not change the percussion notes. This, in itself, is almost a certain sign of an ovarian cyst as against free fluid. Nevertheless, being led to suspect malignancy in the first case by the general bad condition of the patient, I tapped and drew off ascitic fluid. The second case I suspected to be tuberculosis on account of the age of the patient, (fourteen years), and therefore tapped, and got ascitic fluid. At the operations it was discovered that the disease in each case had puckered up the mesentery, and bound the intestines to the back of the abdominal cavity. For this reason the intestines were not free to float on the fluid; hence the tympanitic loins.

CASE XXIX. The patient was sent to me by Dr. W. E. Boardman, who had treated her for several years for chronic pelvic peritonitis. He thought the trouble was due to disease of the tubes, but was in doubt about the possibility of removing those organs in this case on account of long and severe peritonitis. The patient was in a deplorable condition, having been unable to earn her living for several years on account of attacks of peritonitis, and being deserted by her husband on account of vaginal tenderness. Her life was a burden, and she wanted to die. She had had two abscesses opened per vaginam, and had been in the City Hospital two or three times, where fluid had been aspirated from the pelvis. At the operation all the intestines and organs were found firmly glued together so that nearly three-quarters of an hour was consumed in tearing away adhesions to get down to the left ovary. The wall of a small cyst was found matted against the tube and intestine. The tube had become a cicatricial strand. After tearing away a piece of the cyst wall the operation was abandoned as impossible. After vomiting constantly for three days she died. At the autopsy no pus was found, but there was very extensive peritonitis. The ovaries and tubes had become cicatricial tissue, and could not be removed without tearing open the intestines at several points. I cite this case in full because it shows clearly one of the limitations of this operation. After a little successful experience in tearing out universally adherent ovaries or tubes, one is led to suppose that there are no limitations.

I am profoundly impressed by the fact that several of the worst cases recovered when there seemed to be little hope, and that all but one of the fatal cases would probably have recovered if they had been operated on earlier. This leads me to believe that there are still many lives lost for the want of prompt laparotomy. Unfortunately the general practitioner has been over-impressed by recent articles on the "laparotomy craze"; and it is undoubtedly true that ovaries and tubes have been unnecessarily removed by certain operators. I am sure, however, that this view has been greatly exaggerated and when we come to the more fatal class of diseases such as intestinal obstruction, perforation, purulent peritonitis, and the like, the situation is so difficult and appalling that there is no danger of the operations being lightly undertaken or overdone. Now that such operations are clearly established, what is wanted is a realization by the general practitioner of their value. No patient should be allowed to die of an abdominal affection without full consideration of the chances of relief offered by laparotomy.

My experience has made me enthusiastic about the operation, and it seems to me that the community is just beginning to get the full benefit of the fine work of the earlier operators. They have shown the possibility of these operations, and established the technique. And now the present generation has so reduced the mortality that the operation has become of the greatest practical value.

ON SIMPLE EXTRACTION OF CATARACT.

BY HERMAN KNAPP, M.D., OF NEW YORK.

A FEW weeks ago, on February 23d, Dr. Hasket Derby published in the JOURNAL a paper on "The Dangers of Simple Extraction of Cataract."

The paper is a plea for the method of Von Gräfe. The dangers of a simple extraction pointed out by Dr. Derby are real; but this is no sufficient reason to condemn an otherwise superior operation. If a sharp knife is more dangerous than a blunt one, it does not follow that we should prefer the latter, for with proper caution we may have the benefit of the former without its danger. That simple extraction yields the better results, results which, in the successful cases, Gräfe himself called ideal, is beyond controversy. The question for him and his time was: Shall we prefer inferior results in a greater number, or superior results in a smaller number? At the present day I believe this alternative is no longer before us. In simple extraction not only the visual results are better, but also the failures less frequent than in the combined method. Suppuration, owing to antisepsis, has become exceptional; and prolapse of the iris, owing to cocaine, eserine, and a perfected technique, becomes more and more rare, and is little to be dreaded; besides, an iris prolapse can always be removed. The occurrence of irido-cyclitis after Gräfe's operation, which insidiously destroys one eye, and occasionally both, weighs, in my opinion, more than all the dangers still adherent to the simple method.

This question can, however, not be decided by belief and argument, but by experience, experience so large that the element of chance disappears. We have, as Dr. Derby justly remarks, reliable and extensive statistics of the results of Gräfe's operation, but not yet of simple extraction. The Europeans, thus far, have given only general statements.

Dr. Derby in his communication, cites forty-eight simple extractions, the results of which, he correctly says, compare unfavorably with those of other methods. Dr. C. S. Bull, of New York, publishes,¹ in tabular arrangement, thirty-six simple extractions. His results were very good. Dr. Derby further quotes the present writer's report, at the last meeting of the American Ophthalmological Society² (July, 1887), on sixty-eight extractions, with two total losses. This requires a correction, in so far as one of the losses marked in the *Transactions* $\frac{1}{2}$ (mere perception of light) was converted by a subsequent dissection into a good result, namely, $V=\frac{3}{4}$. Since June, 1886, I have practiced simple extraction, as a rule, combined extraction as the exception. Of 154 extractions, 132 were made without, 22 with iridectomy. Accidents during the operation have been less frequent than in

¹ Transactions of the American Ophthalmological Society, 1887, p. 413.

² Transactions, p. 419.

Gräfe's method. Prolapse of the iris occurred in 14 cases, in four it disappeared spontaneously, in four it was removed with scissors, in the others (except one) it was too small to require interference. In no case of prolapse was there any irritation, and the sight was good in all.

One case of the 154 was a failure. It referred to a patient suffering from diabetes (6% sugar) and chronic purulent dacryocystitis. In all the others good vision was restored. The ominous symptom $\frac{1}{2}$ does no longer appear in the record; there was no case of irido-cyclitis.

The *visual results* of the first 100 cases, which I have just compiled for a detailed communication in the *Archives of Ophthalmology*, were as follows:

V = $\frac{20}{20}$. . . in 21 cases	V = $\frac{20}{100}$. . . in 12 cases
V = $\frac{20}{20}$. . . in 18 cases	V = $\frac{20}{200}$. . . in 10 cases
V = $\frac{20}{30}$. . . in 11 cases	V = $\frac{15}{200}$. . . in 2 cases
V = $\frac{20}{40}$. . . in 8 cases	V = $\frac{10}{200}$. . . in 1 case
V = $\frac{20}{50}$. . . in 16 cases	V = 0 . . . in 1 case

I may add that the cases were in no way selected, and that V represents the visual acuteness of the last record entered in the case book.

To obtain high degrees of V, a *subsequent division of the capsule* is necessary in the majority of cases. In these first 100 cases 54 dissections have been made thus far. They were all successful.

If, in conclusion, I may *formulate my opinion* on this subject, it is as follows: Gräfe's method can neither in excellence nor safety compete with simple extraction; it deserves no longer to be the general method, but it will, in a certain number of cases, be the preferable operation, in some the only operation possible.

REPORT ON PROGRESS IN SURGERY.¹

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

LAPAROTOMY FOR INJURY.

SIR WILLIAM MACCORMACK, in the annual oration in May to the Medical Society, spoke on this subject, and advocated an early and more general application of the operation of laparotomy to all intra-peritoneal injuries endangering life, and of exploration of the abdomen in penetrating wounds of the abdomen, gunshot wounds, and traumatic rupture of the abdominal contents without external wounds. Reference was made on this occasion to several cases that had been successfully treated by London surgeons, but it is to Parkes, Morton, Kinloch, and other surgeons of the United States, that we are indebted to the fullest and most recent information on this subject.

Farghar Curtis has sounded a warning note against the indiscriminate application of laparotomy to this class of cases, and has endeavored to point out the indications for operation, and also the contra-indications. He has pointed out that if the operation is performed while the patient is in a state of collapse, that the result will almost inevitably be fatal, and will bring discredit not only upon the operative procedure, but also on the operator. That a serious injury of any abdominal viscera may be successfully treated by laparotomy has been shown by Burckhardt, of Stuttgart,

who early in the year reported a case in which death from hemorrhage was averted by exposing and plugging a deep incised wound of the liver.

LAPAROTOMY IN CASES OF PERITONITIS WITH PERFORATION OF INTESTINE.

Dr. Th. Eschar reports in detail³⁷ five cases of perforation, two of which recovered, although purulent peritonitis was present at the time of operation. In both the perforation was closed at the operation. Eschar discusses at length the question, in case of perforation or necrosis requiring resection, of whether immediate closure of the intestine by suture, as advocated by Krönlein and Mikulicz, is indicated in all cases. His conclusions are that in *traumatic* cases of peritonitis with perforation, laparotomy and intestinal suture, with resection, if necessary, should be the rule; but for *pathological* cases, the extent of operative interference justifiable depends on the conditions of each individual case, and that the treatment of these cases is closely analogous to that for gangrenous hernia. Eschar also states that the collection of free gas in the abdomen, which has frequently been designated as one of the most certain signs of "perforation-peritonitis," is occasionally absent. In two autopsies the injury was in the jejunum, in one a double complete transverse separation of the intestine; and the writer believes that in cases of perforation where free gas is absent, or where the appearance of symptoms denoting its presence are delayed, one can assume with certainty that the jejunum is the seat of the lesion.

LAPAROTOMY FOR SUPPURATIVE PERITONITIS.

Mr. Barwell has recently reported a case³⁸ of recovery from a suppurative peritonitis in a man who had been struck on the abdomen, but who seemed but little hurt. Five days afterwards, while stooping, he felt a severe pain in the abdomen, vomited, and passed a little dark-colored urine. The next day he entered the Charing-Cross Hospital, and a laparotomy was done, the abdomen being washed out with ten pints of distilled water at a temperature of 99°. A quantity of pus was evacuated, and the abdomen was closed completely, no drainage-tube being used. Mr. Barwell points out that the operation has been performed fourteen times, though not always done for the same trouble. The precise circumstances of the case have been, various ulcers, ruptures of the intestinal tract or of an ovarian cyst. He considers that to attempt to drain the back of an abdomen through a drainage-tube in the anterior wall is an absurdity, and may be a source of direct injury. He considers, if there is much distension following an operation, or if it is thought necessary to drain the abdomen of collected fluid, that it is better to remove the lower stitches and allow the fluid to escape in the male; in the female, he thinks that vaginal drainage would be indicated. Mr. Barwell claims for Mr. Hancock the credit of opening the abdomen for suppurative peritonitis.

LAPAROTOMY IN PERITYPHLITIC ABSCESS, WITH ESPECIAL REFERENCE TO PERFORATION OF THE APPENDIX VERMIFORMIS.

This paper by R. F. Weir consists³⁹ of a critical an-

³⁷ Wien. Med. Wochenschr., 1887, Bd. xxxvii, s. 18-22.

³⁸ Lancet, November 5, 1887.

³⁹ N. Y. Med. Rec., June 11, 1887.

¹ Continued from page 320.

alysis of ten reported cases, and a plea for earlier and more decisive treatment. He concludes that anaesthesia in these cases should be very limited in degree, or replaced by cocaine, and recapitulates the following propositions: due to inflammation or perforation of the appendix, (1) That the generality of perityphlitic abscesses are vermiformis. (2) That the mortality in such lesions is greatest prior to the third day. (3) That as soon as it can be recognized, pus should be evacuated extra-peritoneally if possible, or by lateral laparotomy, and the cavities drained. (4) That if aspiration fails to detect pus where a tumor exists, it is wiser to make an early extra-peritoneal exploratory incision. (5) That where general peritonitis is progressing, with any history of a right iliac pain, a limited lateral (preferably) or a median laparotomy should be made to explore the region of the appendix within forty-eight hours of the inception of the disease. (6) That if pus is thus recognized, it should be evacuated and a drainage-tube inserted without toilet of the peritoneum.

THE USE OF HOT WATER WITHIN THE PERITONEAL CAVITY DURING AND AFTER LAPAROTOMY TO PREVENT SHOCK.

Towels wrung out in hot water to protect the intestines when turned out of the peritoneal cavity has been used a long time; but W. Gill Wylie⁴⁰ advocates the use of water at a temperature of 105° to 110° for the purposes of irrigation. He considers its use in a prolonged operation to be a powerful and efficient agent, lessening, if not preventing, the effects of shock. It further acts as an efficient haemostatic for oozing points too numerous and small to tie.

PENETRATING GUN-SHOT WOUNDS OF THE ABDOMEN.

A very complete and careful review of the cases now on record of this class of injuries⁴¹ treated by laparotomy gives the following interesting information concerning the value of this method: Total number of cases, 71; total number of recoveries, 30 (42 $\frac{2}{3}$ %).

CLASS I. Operation within twelve hours after injury, 38 cases: recoveries, 19 (50%); deaths, 19.

CLASS II. Operation later than twelve hours after injury, 20 cases: recoveries 4 (20%); deaths, 16.

CLASS III. Interval between injury and operation unknown, 13 cases: recoveries, 7 (53 $\frac{1}{3}$ %); deaths, 5; doubtful, 1.

Seat of injury, 57 cases: small intestines, 30; colon, 13; stomach, 6; liver, 5; duodenum, 2; kidney, 2; rectum, 1; bladder, 1.

Of the symptoms recorded in the reports of 57 cases vomiting, occurred in 15, including 4 cases of hæmatemesis. Hepatic resonance was noted in 3, tympanites in 4, shock in 15. In 4 cases shock was stated to be absent.

COLOSTOMY OR INTESTINAL RESECTION.

The question to decide where one is compelled to resect an intestine, whether immediate suture of the intestine or an artificial anus is the most desirable treatment, is often a difficult one, especially where ascending colon or ileum is involved. Hahn's statistics in cases of resection of the colon seem to favor an artificial anus.⁴² Of these cases, in 18 the intestine was sutured (10 deaths, 55.5%); while in 8 cases of

artificial anus 3 deaths occurred (37.5%). In discussing these results, Hahn⁴³ states that although these results favor the formation of the artificial anus, still one must, before deciding in favor of this operation, learn the mortality from the secondary operation for closing the latter. In favor of extensive resection, he reports two cases of successful removal of part of the colon and ileum for sarcoma; in one, about one meter of the colon, cæcum, and ileum. In both these cases an artificial anus was made. The following are the cases of resections where one meter or more has been removed: In 1884, Baum⁴⁴ removed 1.37 meters from the small intestine of a patient, aged forty, for strangulated inguinal hernia, fecal fistula, and mesenteric abscess; immediate suture; death at end of four months from marasmus, from malnutrition.

In another case, Koeberle, in a woman aged twenty-two, on account of obstruction from several strictures, resected altogether about two meters of small intestine with success; after-result not known. The only other case found is that of Kocher's: Patient a man, aged fifty-seven, with gangrene from a strangulated inguinal hernia; 1.60 meters removed from small intestine; primary suture; complete recovery.⁴⁵ It is extremely important to know in this class of cases how much intestine can be resected with safety. It would seem that a loss of a large extent of small intestine is better borne than an equal amount of ileum and colon. Whether a portion of the colon is more fatal than an equal amount of small intestine, is not yet decided.

THE RADICAL CURE OF HERNIA.

A long series of papers⁴⁶ read at the annual meeting of the British Medical Society at Dublin by Mitchell Banks, MacEwen, Arthur Barker, and others, proves that the method of free incision has, in the practice of most surgeons, superseded the subcutaneous method. These papers together with their accompanying tables of cases, show the comparative safety and the general good results, as far as can be determined at present, of the more modern methods of procedure, but there is still much difference of opinion as to the treatment of the sac, and as to whether the canal and external ring should be closed by sutures or not. Banks believes that all cases in children should primarily be subjected to treatment by truss before one proceeds with the more severe operative procedure.

SPLENECTOMY.

The spleen has been successfully removed a number of times during the last six months. Leonard, of Philadelphia, has recently reported a case of the successful removal of an hypertrophied spleen, and asserts that in twelve out of seventeen cases that have been recorded since the year 1881 this operation was successful. Other successful cases have from time to time been published by Myers, Severeanu at Bucharest, and Sir Spencer Wells.

THE TREATMENT OF HÆMORRHOIDS BY THE FORCIBLE DILATATION OF THE ANUS.

steel, which can dilate the anus so that four fingers can easily be admitted. This is done slowly and carefully, that no tearing of the tissues may occur, and is made to dilate it in various directions. When there is any considerable loss of blood he uses the thermocautery, but ordinarily finds that there is no necessity for its use, and there is a rapid subsidence of the symptoms and a complete recovery of his patients.

BASE-BALL PITCHER'S ARM.

A. H. P. Leuf has contributed an interesting paper on this subject,⁴⁸ in which he clearly sets forth the pathology of this affection. It seems that in its severer and more chronic forms we have a painful osteitis and periostitis, combined with a strain of the ligaments and muscles. In order to give the ball different curves individual sets of muscles are called into play. For instance, to give the in-curve, the pectoralis-major, the biceps, brachialis anticus, and flexors of the forearm; the out-curve is accomplished by the pectoralis-major, coracobrachialis, infraspinatus, teres-minor, and the ulnar muscles; the down-curve strains especially the pectoralis major, trapeziums, deltoid, and serratus magnus; the up-curve is caused by the pectoralis major, biceps and supinator brevis. All of these movements are given in a quick, jerky manner, bringing a great strain on the individual sets of muscles besides tending to separate the bones at the outer part of the elbow-joint, this being prevented by the biceps, supinator longus, and extensor carpi radialis longior.

The symptoms produced by this affection are soreness, tenderness, myalgia, and severe continuous sickening pains, due to involvement of the bone. It is, of course, only in the long standing cases that there is an involvement of the bone.

The treatment should be prophylactic, and the pitcher should each day practice in the sun. Liniments, massage and rubbing are all useless. Heat is the best application, with elevation of the limb. This will often relieve the pain in these cases. The main point in treatment is regular exercise, and not rest.

SUBCUTANEOUS INJECTION OF BLOOD, SALT-SOLUTION INFUSION AND INTRAVENOUS TRANSFUSION.

The alarming symptoms often following the ordinary method of intravenous transfusion, such as fever-chills, albuminuria and hamoglobinuria, etc., show conclusively that it is not one unattended with danger. These symptoms von Ziemssen considers not due to the injection of the defibrinated human blood, but are wholly due to the perishing blood with its ferments, fragments of fibrin coagula and air bubbles which are also injected into the circulation. Von Ziemssen proposes⁴⁹ to avoid these dangers by injecting the blood into the subcutaneous cellular tissue instead of into a vein. The blood should be with extreme aseptic precautions thoroughly defibrinated. It should be kept at a temperature between 37°-40° Cent. With a small syringe under chloroform narcosis 25 ccm. of the prepared blood is injected deep into the subcutaneous tissue, (thigh preferably) which is then vigorously massaged by an assistant. The massage is an important element in the operation. For each fresh injection a new

puncture is made. The pain subsequent to the operation is alleviated by an ice-bag, and the patient kept at rest. The writer states no limit to the amount to be injected, which in one case amounted to 350 gms. by fourteen punctures. His directions are to use the entire supply of blood at hand. The process is without danger. Suppuration has occurred in only two points of puncture, and from causes easily to be avoided. In no case has rigor, fever, albuminuria, etc., been observed. The subcutaneous tissue filters from the blood the coagula, air bubbles, and other elements of danger, while the red corpuscles pass rapidly into the circulation. After a few days all traces of free blood at the site of injection is gone, and the circulating blood shows an increase of hamaglobin. For twenty-four hours this amount increases to sometimes double that observed before the injection, but during the following four to five days falls slowly to an amount which then remains constant, but always in excess of the original amount. By repeated injections it can be eventually raised to the normal amount. There is also a corresponding increase of the red corpuscles. Von Ziemssen has obtained by this method recovery from severe chronic anemia, from different causes, after a month's treatment, but has not yet tested it in acute cases, after violent hemorrhage, although he considers it suitable for such patients. If blood cannot be used he recommends a salt solution. It is easier than the intravenous method, and absolutely without danger, and ordinary spring water which has been sterilized by boiling, can be satisfactorily used. Since absorption is very easy, anesthesia is not required, and 600 g. water can be injected through four to five punctures. This surmounts the first danger from emptiness of the heart and consequent cardiac failure, and gives an opportunity for the preparation of the blood. The salt injection in really severe hemorrhages seems only to postpone a fatal end, and new blood must be obtained from some external source as soon as possible.

INCREASED BONE FORMATION BY ELASTIC COMPRESSION.

Helfferich claims that his experience during the past six years in numerous instances has convinced him of the utility of this practice in cases of retarded or insufficient callus formation after fractures, necrosis with deficient bone formation, or resulting spontaneous fracture. At the sixteenth German Surgical Congress⁵⁰ he described his method based on the facts that both physiological and pathological bone-growth is increased by hyperemia, and that a young bone may thus be made thicker and longer. An elastic rubber tube is passed around the limb proximally from the affected area, and fastened so that a slight venous hyperemia results from the limited constriction. If painful it can readily be loosened by the patient. A bandage above and below the diseased part localizes the hyperemia. Splints or plaster fixation is also used. At first the compression is applied for hours. Soon the bandage is worn continuously, and patients soon become accustomed to it. Shortening following fracture or infantile paralysis was thus improved. A normal tibia had been lengthened in a girl aged fifteen to correspond in length with its opposite, which was elongated from disease. The method is contraindicated in fractures with large granulating wounds,

tubercular osseous disease, or after operations for malignant tumors.

TREATMENT FOR FAULTY UNION OF FRACTURES OF THE CARPAL EPIPHYSIS OF THE RADIUS.

Such results from this class of injuries not infrequently force the patient to seek treatment for the resulting impairment of motion. Massage, passive motion, electricity, etc., are unsuccessful, and an operation, either of chiselling through the united epiphysis, or freeing the tendons, is the only remaining resort. The limitation of pro- and supination results in part from the faulty position of the fragments, in part to a coincident fracture or fusion of the ulnar epiphysis, which easily results in excessive callus formation and bony ankylosis of the radio-ulnar joint. L. von Lesser¹ reports an excellent result from resection of the capitulum ulnæ, giving the details of operation. He claims also that to prevent such faulty union (in such fractures of the radius) the forearm should be treated in full supination with ulnar abduction of the hand.

(To be continued.)

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

REGULAR MEETING March 5, 1888, DR. F. H. WILLIAMS in the chair.

DR. A. T. CABOT exhibited a patient upon whom he had operated for ankylosis of the lower jaw with most gratifying results.

DR. F. I. KNIGHT presented a paper upon
THE SELECTION OF A CLIMATE FOR PATIENTS WITH
PULMONARY TUBERCULOSIS.¹

DR. F. C. SHATTUCK expressed his appreciation of Dr. Knight's valuable paper, which is exactly what is wanted.

It is an interesting fact that pneumonia is extremely fatal in the higher regions of Colorado. Unless the patient can be got down lower promptly there is little hope for him. Apparently in the rare atmosphere if any considerable portion of the lung is thrown out of function what remains is not sufficient for the maintenance of life.

The speaker had two patients wintering at the Adirondacks, with benefit; and asked for Dr. Knight's opinion with reference to this region. Saranac certainly has one great advantage quite apart from purely climatic consideration in the presence of a man so skillful and experienced as Dr. Trudeau. The great importance of taking and following good local professional advice was very properly dwelt upon by the reader.

DR. WHITTIER thought that a certain class of cases were greatly benefited by a residence of a winter in Lake Saranac region. One of his patients who spent the winter there and gained fifty-six pounds, returned with his lungs in a normal condition, and

spent the following winter in Boston without return of the trouble.

DR. J. STEDMAN had sent many patients to Colorado, always with marked benefit. For a preliminary trial he advised, in many cases, Sharon, Mass. Florida had not proved an advantageous climate. Aiken, S. C., had proven very beneficial.

DR. VINCENT Y. BOWDITCH spoke of the influence of certain places near Boston upon pulmonary diseases, special mention being made of the towns of Wellesley Hills, and of Sharon, both within twenty miles of this city. He did not doubt that there were other towns to be found near Boston whose climate and soil were beneficial in phthisical cases; but his father in former years had sent patients to Wellesley Hills, where they had improved often very markedly. In his own experience he had had patients improve by residence in both of these towns, the soil being of a very porous nature, while both places are sufficiently far from the coast not to feel the effect of our harsh east winds. While giving the preference naturally to a more decided degree of climate, where circumstances permit, Dr. Bowditch felt the importance of bringing forward the fact that there are places nearer home where poorer patients may go with a hope of improvement.

Dr. Bowditch regretted the absence of his father, who had requested him to ask what the experience of the members of the Society had been as to the wisdom of a patient's returning to this climate after improvement, or apparent cure, elsewhere. In his own experience he could say that almost invariably relapses occurred where the trouble had been situated in the apices of the lungs, but that the contrary had frequently been the case if the base of the lung had been affected.

As to the comparative value of places in New Hampshire as resorts for phthisical patients, Dr. Bowditch preferred Bethlehem, on account of its altitude, its dry air, and exposure towards the west and south.

DR. E. O. OTIS said he had hoped that Dr. Knight would have said something more in his paper as to the length of residence for the consumptive in the climate selected for him. When could he come home and stay at home with safety; and what are the conditions which require a permanent residence in the new climate? That many return too soon, and either have to go back again, or die at home, we all know. He had no doubt that Dr. Knight could give us many such examples from his large and long experience. He must confess that he was of the conviction that for many cases a permanent residence in the climate found to be the one best suited to the patient and his disease is the only safety.

The improvement of the patient in the climate chosen for him, or in any health resort, seemed to him to depend also largely upon his former manner of life, his tastes and idiosyncrasies, and how well they correspond with the habits suitable for a consumptive in an out-door climate. One person is from youth fond of and used to much out-door life; is active. Such a one takes naturally to his new life, and is likely to gain rapidly and get well. Another is of sedentary habits, indolent, lives much in-doors. For such a one it is hard to change his old habits and ways. He is inclined still to stick to his old ways of in-door life and inactivity, and consequently does not do so well.

¹ See page 343 of the Journal.

² Centbl. Bl. f. Chir., 1887, xiv. s. 15.

As an illustration he had in mind two brothers who went to Colorado for phthisis, the one of active habits, the other of sedentary ways. The former took a cattle ranch and lived on it, and, to the best of his knowledge, is now well; while the latter went to Colorado Springs, was much with his books, and is now in a hopeless condition.

Incidentally this leads to the realization of the importance of training children in such a way that they shall form a love for, and habits of out-door life.

He had been deeply interested in Dr. Knight's excellent paper, and wished he might have more such valuable information upon this most important subject which would enable us with greater accuracy and care to adapt the climate to the patient whom we advise to flee somewhere for his life.

DR. AYER alluded to the risk of sending patients in whom there was tendency to severe hemorrhages to Denver. The testimony of the residents there was that sudden death from pulmonary hemorrhage was very common.

Several of the members present alluded to the advantage of a continued residence in Sharon, Wellesley, and adjoining towns near Boston for those patients whose circumstances did not permit the long journey to Colorado.

DR. KNIGHT said, in conclusion, that he had seen patients who had done well in the Adirondacks, though he preferred higher elevations, where there were no contra-indications. He found that patients objected very strongly to wintering there after one trial, on account of dulness of the life and want of accommodations.

In regard to the places very near home, such as Wellesley and Sharon, in this State, he should say that a patient would be much better off in them than on the coast; the same may be said of places in New Hampshire and Vermont, but the great difficulty was in leading an out-door life in any part of New England. The climate was too rough. In regard to the effect of returning East from a high elevation to reside after the pulmonary disease had been arrested, Dr. Knight said that he preferred that a patient should not do it, but should remain where the arrest of disease took place, but that he knew several who had done so, contrary to advice, and yet had remained well.

In regard to the cases of fatal hæmoptysis, which has been reported as occurring in high altitudes, it would probably be found that they were cases of advanced disease in which a large vessel had ruptured into a cavity. Such patients should not have been sent to a high altitude.

DR. WADSWORTH showed a specimen of melanotic disease of the choroid, which had existed for a considerable time, and which he had successfully removed.

DR. PAGE read a circular regarding the establishment of an asylum for the inebriates.

Dr. Page observed: In reply to Dr. Knight's inquiry that his knowledge of inebriates and their needs came from three sources, to wit: that gained from experience while connected with an institution for the insane; also with one for the treatment of nervous people, and from the general practice of medicine—all of which sources enabled him to say that, so far as his experience went, the present methods, as now pursued for the care and reformation of these unfortunate beings, and especially for those who were really free from criminal habits and tendencies—and there were

a definite number of such people amongst us—were inadequate and unwise, if not unjust, if the cure and reformation of the individual was to be hoped for. This, evidently, does not seem to be the end in view under present arrangements, judging from the large number and frequency of commitments to both penal and reformatory institutions: although he would say here that it is probably all that can be done under existing circumstances. What he hoped for was something better, and an improvement on what is now found to be inadequate for present wants.

He was aware that a claim had been advanced elsewhere that such an asylum as was contemplated by the proposed bill, indicated in the circular read, was not especially needed for these persons, the present arrangements being ample and fairly satisfactory. So far as common drunkards of vicious or criminal tendencies were concerned, this was probably true—the accommodations were fairly suitable—but it was not true of a class who, by reason of the only places to which they could go, were of necessity obliged to be committed to either the prison, the house of correction, or the reformatory at Concord, and there mingle with criminals, and subjected to the same rules and regulations, or else be sent to the insane asylum—all of which places were manifestly not the proper places for their care or hoped-for recovery. The influences upon them all were notoriously bad, and especially so upon the young men. If sent to a proper asylum, they would be saved from association with criminals of various kinds, with its attendant perils, and from the stigma which inevitably attaches itself to one who has been in an insane asylum, however unjust this may be. Then, again, every superintendent of an insane asylum knew that within a very short time after admission these cases cleared up from the mental perturbation and benumbing effects of alcoholic stimulation and intoxication, and became sane people, mingling with the insane—a source of trouble to the medical officers by reason of their restlessness, discontent, complainings, etc., and their generally bad influence upon the insane.

If the continued and protracted habit of using alcoholic liquors is in many instances a disease—and this is now the opinion of the alienist, as well as the neurologist, why shouldn't such people as may be suffering from this form of disease have accorded to them the same opportunities and facilities for their care and cure, if this be possible, as the insane, but without the objectionable feature of associating with insane people, or the baneful effects pertaining to penal institutions. He himself believed that they should have, and in this view he was sustained by a large number of good people, professional, as well as laity, who had become deeply interested in this subject, and who also felt that the existing arrangements were not in accordance with the dictates of humanity. He hoped the Society would give the matter thorough consideration. If they did, he felt that they would arrive at similar conclusions. He might adduce instances in illustration of his remarks, having in mind one case which was sent to the reformatory at Concord, and who was subjected to the same rules and regulations as the criminals therein confined—a kind of treatment which was hardly fair to the man or conducive to his highest good, though perhaps a necessity in a certain sense, as he had neither vicious tendencies, nor was a criminal in any sense, though addicted to drinking spirits.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, APRIL 5, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year, for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

PATHOGENY OF HYSTERIA.

It was inevitable that a disease presenting such a variety of aspects and phases as hysteria, involving disorder of the functions of the nervous system in all its spheres — intelligence, mobility, sensibility, and visceral neurility — always bizarre in its behavior and rooted in the personality and psychical life of the subject, should be a puzzle to the ancients, who understood so little of the nervous system, and that absurd demoniac and other theories should be framed to account for it. Apart from the attribution of this multifiform malady to demoniacal possession, and especially to that particular phase of the latter known as witchcraft, doubtless the great error of the past ages has been the almost exclusive ascription of this disease by physicians to morbid uterine influence. It is, in fact, but recently that the uterine theory which has, unfortunately, given its name to this disease has begun to be discredited and abandoned (as it certainly has been) by all who have made a study of the disease in the light of modern neurology, and the frequent occurrence of undoubted cases of hysteria in the male has been enough of itself to overthrow completely the old theory.

It is undeniable that the symptomatic tableau of hysteria suggests as the starting point of the morbid phenomena some lesion of the central nervous system. This is, presumably, of a functional or dynamic, rather than of an organic nature, as has been proved by numerous autopsies of persons dying in confirmed hysteria. Pathologists have long been familiar with these *læsiones sine materiâ*; such, in fact, constitute the basis of epilepsy and all the other so-called functional nervous maladies. It is impossible in the present state of science to explain these modifications in the gray matter of the cerebro-spinal axis, which are molecular in their character, and connected with the assimilation and discharge of force. Grant, moreover, that the modifications alluded to are characterized by instability, vulnerability, or "want of tone" in the ultimate nerve elements, which thus become too easily

responsive to peripheral and visceral irritations, with also the necessary factor superadded, that there is a deficiency of the higher cerebral inhibition, and we have a basis on which the pathogeneity of hysteria may be founded.

In what part of the nervous system shall we locate the principal seat of this malady? Deranged states of the vaso-motor centres cannot explain the cardinal symptoms of typical hysteria, as Vulpian has well shown,¹ nor can even dynamical lesions of the mesocephalon, which Vulpian supposes to be especially interested in the sensory and motor phenomena. At the time of the writing of Vulpian's treatise, the doctrine of cerebral localizations was yet in the embryo; later developments in that department of science have shed a flood of light on many obscure nervous affections. Many of the mild forms of hysteria have been referred to "spinal irritability," but no condition of "erethism" or "anæmia" of the spinal medulla or mesocephalon can explain those well-developed cases where, with more or less obnubilation of the special senses (sight, hearing, smell, taste,) there is complete hemianæsthesia. Nothing, as Charcot has shown,² can account for such cases but a focal lesion of the cortex cerebri. Moreover, many singular forms of monoplegia, such as have been described in Charcot's latest work,³ can only be understood as manifestations of a dynamical lesion of a limited area of the motor part of the cortex. The psychical disturbances which accompany grave hysteria, the clonus, and other forms of hysterical pain, the disorders of consciousness during hysterical attacks, also clearly indicate abnormal conditions of the cerebral hemispheres. Such considerations seem to justify the classification of hysteria as a cerebral neurosis.

When the physiologist has pronounced the words "dynamic molecular modifications," "nutritive disturbances," he has not yet said the last word respecting the cerebral disease which finds expression in hysterical manifestations, and able and ingenious thinkers have pushed the investigation further, and endeavored, from known laws of organic molecular physics, and known biological and pathological principles to deduce the pathogeneity of hysteria. Among recent attempts in this direction is a communication of Dr. Mary Putnam Jacobi to the New York Academy of Medicine.⁴ In this interesting paper the writer presents the following as the series of conditions which succeed each other in the cortex of the hysterical brain: (1) A diffused deficiency in storage power: deficiency shared more or less with other nerve tissues, usually congenital, sometimes acquired; (2) nevertheless, the effecting of abundant storage in the sensory centres, under the permanent stimulus of centripetal impressions; (3) deficient centrifugal activities, mental and motor, or exhaustion of mental and motor areas by exertion performed with inadequate storage material; (4) deficient

discharge of sensory centres, which continue to store material under the stimulus of centripetal impressions, but fail to decompose and eliminate this sufficiently when centrifugal movements diminish in activity; (5) hyper-excitability of the sensory centres, which contain an excess of force-material produced during registration of impressions, and not broken up by their transmission; (6) tendency on the part of these surcharged sensory centres to inhibit the activities of the rest of the fore-brain.

PAINLESS PARTURITION.

"Unto the woman he said: I will greatly multiply thy sorrow and thy conception. In sorrow shalt thou bring forth children, and thy desire shall be to thy husband, and he shall rule over thee."

THE aversion caused in the minds of certain women by the sentiments contained in the last clause of the above verse is, perhaps, the cause of their disaffection with the other sentiments expressed in the same connection by the Jewish law-giver. At all events, there are not wanting individuals, mostly without the medical profession, who protest against all suffering in parturition as unnecessary, and claim that the normal physiological woman should, and what is more, does suffer no pain whatever in the act of giving birth to a child; in other words, that a woman is in every way quite "as good as a man."

Painless or nearly painless labors have been recorded, and most physicians have in their own experience met with cases partaking of this nature. That they are, however, contrary to the usual experience of the race is evinced by the very terms in ordinary use to describe the act of parturition; namely, *labor* and *pains*. If normal labor is painless, then we must assume that normal labor is as rare a thing as, according to certain thinkers, is a healthy man or a sane man; that is, practically, non-existent.

More than eighty years ago, Dr. Wm. P. Dewees, of Philadelphia, announced the doctrine of painless parturition. He averred that the circular fibres of the uterus were not attended by pain in their contraction; that such pain as was experienced in labor was from the contraction of the longitudinal fibres. He further claimed that the changes of degeneration produced by civilization and refinement in the uterine structure were confined to the longitudinal pelvis.

"Why a particular set or given direction of fibres should have suffered more than another," he says, "may be impossible to determine; but that they have we believe to be most certain. This change, however, is by no means confined to the uterus, as every straight muscle of the body appears to have participated with it, since it is admitted that the man of the civilized world has lost much of his original strength."

This last illustration, adduced in support of his argument, seems rather an unfortunate one, as the trained athlete is certainly a better specimen of strength and endurance than can be found in any of the primitive races of men. Dewees does not appear to have contemplated anything more than a diminu-

tion of pain, not its abolition, and his recipe therefor, after condemning as useless opium and the hot bath, was copious bleeding to the point of syncope.

Engelmann, in his "Labor among Primitive Peoples," states that among primitive peoples, still natural in habits, and under conditions favorable to their physical organization, labor is short and easy, accompanied by few accidents, and followed by little or no prostration. The Modoc squaw, entirely innocent of the sophistications of civilized life, suffers, this author says, but an hour or so; the Mexican Indians, who are half-civilized, linger three or four hours in labor, while a nearer approach to civilization gives a more trying ordeal, the squaws at the Green Bay Indian Agency having many deaths in labor, attributed chiefly to malpositions, rather than to any bony deformity of the mothers. The evidence of travellers, while admitting a brief labor for most barbarous women, does not warrant the assumption that such labors are painless.

The delivery of the domestic animals is, we believe, usually accomplished without protracted suffering or any considerable degree of mortality, though the cow and the mare sometimes suffer great distress (is it because they have shared with their masters the perils of civilization?). That the act is in the wildest of animals ever a comfortable one, however brief, is exceedingly doubtful.

The foregoing remarks are suggested by the fact that one of the books written for the instruction of married women in matters pertaining to the generative system¹ announces, as we believe, an entirely fallacious doctrine on this point of painless parturition. Books of the character referred to probably have their mission, and if written judiciously, and confined to the hygiene of married life and the pregnant state, are not to be discouraged altogether, as, if not these, more objectionable works on similar subjects are bound to be read by a good many women, either from motives of curiosity, or from a commendable desire to know how to conduct themselves. With the chapters in "Tokology" relating to the conduct of labor we have, of course, no sympathy. In time of labor, if not throughout pregnancy, every reader of such a book can have medical attendance and direction, and the physician, if he is worthy of any confidence, can be trusted to decide whether to give ergot, to leave the cord untied, or even to use the instruments, which, under the prescribed régime, are "almost never needed."

But, together with much of established hygienic value that is recommended in this book, such as exercise, diet, and bathing, there are other things, to say the best of them, of unproved theory, recommended with the assurance that, following them, a woman may confidently expect a *painless, because normal, labor*. In the matter of diet, for instance, this author strikes off all meats, "owing to their stimulating elements and their effects on the formation of character." She thus

¹ Tokology, a Book for Every Woman, by Alice B. Stockham, M.D. Boston, 1886.

eliminates all "bone-forming foods" according to the theory of a "practical chemist" of London, practised with success on his own wife in 1841, that the bones of the child can thus be made soft and pliable. Sugars and fats are with better reason proscribed, and the patient is left to acid fruits and rice. We have reason to know that women of intelligence, reading this book, have been kept not only in a state of constant introspection throughout the period of their pregnancy, but have suffered from this enormous limitation of their diet in the delusive hope thereby to have a perfectly painless labor.

That civilized and luxury-loving women have departed very far from the conditions of life under which labor is a purely physiological process, is freely admitted. That much can be done for the individual, and still more for her daughters through successive generations, in the way of a return to more normal parturition by a careful management of the hygiene not only of pregnancy, but of the whole sexual period of life, is also true. But that when this has been done, women will then have children without any consciousness of pain, is by no means a demonstrated fact; and the teaching that every woman, by nine months of fasting, even if it be accompanied by an otherwise rational regimen, may expect to secure painless labor in her own person is not only fraught with disappointment, but with more positive injury from the weakening of the powers by the withdrawal of proper food.

A LAW DISPENSARY.

A "LAW DISPENSARY" has been established in New York "under the auspices," says a contemporary, "of reputable lawyers in connection with the Rev. Mr. Goss's People's Mission," for the benefit of poor people who require legal advice and cannot afford to pay for it. The sorts of law that the "poor but honest" classes of the community need are obviously pretty limited. It is sad that the very nature of the case so completely shuts out our brethren of the legal profession from the luxury of doing good *in kind* to the worthy poor—that luxury which is so superabundant with the medical profession. It is to be hoped, however, that in the dearth of opportunity to give away advice on "real property," "contracts," "wills," and similar subjects, the philanthropic law-dispensers will not devote themselves to giving instruction as to actions of tort to such of their patrons as are also constant attendants at the multitudinous medical dispensaries. Too much of such advice has been given by lawyers in the past, and it is better dispensed with than dispensed.

MEDICAL NOTES.

—The Medico-Chirurgical College, of Philadelphia, holds its tenth annual commencement Friday, April 6th. The previous evening the Alumni Association will entertain at dinner Surgeon-General J. B. Hamilton, of the Marine Hospital Service.

—Prof. Paget carries in his obstetric bag an ergot mill, resembling a small coffee mill, compact in form, and designed to grind up ergot freshly for use. He claims that only the freshly pulverized ergot is reliable, and he thus secures it when wanted without depending on tincture and other liquid preparations, fetched from the druggists.

—At the annual meeting of the Medical Society of London, held March 3d, it was announced that the Fothergillian prize of a gold medal of the value of twenty guineas, had been awarded to Dr. Hobart A. Hare, of Philadelphia, for his essay on "The Pathology, Clinical History, and Diagnosis of Affections of the Mediastinum other than those of the Heart and Aorta."

NEW ENGLAND.

—A fatal accident occurred last week at the works of the Thomson-Houston Electric Company, of Lynn, Mass. A young man, twenty-two years of age, received a shock from acireuit on which there were fifty-two arc lamps. The electric current which passed through his body being equal to about forty horse-power, his death was instantaneous. Artificial respiration was kept up for an hour by some of the officers of the company, but without avail. The unfortunate man was taking readings from two instruments, which should have been placed so far apart that he could touch but one at a time. Instead of this, by his own carelessness, it is said, the instruments were placed close together. His hands were both badly burned.

NEW YORK.

—The College of Pharmacy of the City of New York held its fifty-eighth annual commencement at Steinway Hall on the evening of March 28th. There were ninety-five graduates, and the address to the class was delivered by Gen. W. T. Sherman.

—At the last meeting of the Nineteenth Century Club the "mind-cure" was the subject of discussion. A Miss Bell advocated the claims of the mind-cure system, and Dr. Wm. A. Hammond replied. In the course of his remarks he said that he should like to see the speaker arrest, without the use of drugs, the progress of diseases like small-pox or yellow fever, or without mechanical apparatus successfully repair broken limbs. He also offered to give \$1,000 to any mind-curer who would produce four patients who, after receiving injections of certain drugs did not show the natural effects of these agents on the system. The discussion was concluded by W. A. Purrington, Esq., Counsel for the Medical Societies of the State and County of New York, who spoke in favor of restrictive medical legislation.

—The death of three children from diphtheria during the past week in a single family on Columbia Heights, the finest place of residence in Brooklyn, together with the probably fatal illness from the same disease of the professional nurse who was in attendance on the children, has alarmed the residents of that city and stirred up the local health authorities.

It is several years since contagious diseases have been so prevalent in Brooklyn as during the last three months. After the early winter outbreak of small-pox had been in a measure controlled, the number of cases of diphtheria rapidly increased, and in January 299 cases, and 114 deaths from it, are reported. During February there were 261 new cases, and 86 deaths; while the record for March is said to be nearly equal to that of January. Scarlatina has also been very prevalent, and since the first of the year nearly one thousand cases and over 175 deaths have been reported.

—The unlucky steamship *Britannia*, running to Mediterranean ports, which brought cholera into New York harbor nine months ago, recently arrived with small-pox on board, and has been prevented from coming up to the city by the health authorities until the effects of vaccination could be observed on the passengers.

Miscellane.

ELECTRICAL TREATMENT OF SEWAGE.

A WRITER in *Science* describes the process recently patented by Mr. William Webster, F.C.S., of purifying sewage by means of the electrical current. The pollution of rivers by the sewage of large cities is a constant source of danger to health; and, according to the *London Standard*, £1,000,000 is to be spent in attempting, by the employment of chemicals, to purify the London sewage. Mr. Webster's plan consists in sending a current of electricity from metallic electrodes through the sewage. The result, in experiments made on a very small scale, is to set the solid particles held in suspension in motion, "a kind of procession taking place from the top downwards, and from the bottom upwards. The sum-total of the movements consists in landing the suspended particles at the top of the liquid." "So prompt is the effect of the electric current that in twenty minutes a volume of opaque sewage becomes perfectly transparent, except at the top, where the organic matter collects in a semi-solid form." "From results already obtained it is calculated that the cost of the electrical treatment of the London sewage would be about £25,000 per annum. The annual outlay for chemicals is expected to be £18,000 for lime and iron, and £12,000 for permanganic acid, making a total of £30,000, a balance of £5,000 in favor of the electrical method. It would seem that Mr. Webster's experiments have, as yet been on a small scale. If the practical results bear out what has been done in the laboratory, the process will be of the greatest importance.

A CLINICAL ANALYSIS OF SIXTY-FOUR CASES OF POISONING BY LEAD CHROMATE USED AS A CAKE-DYE.

DR. D. D. STUART, of the Jefferson Medical College, who has previously published notes of cases of lead poisoning occurring through this channel, has recently presented to the Philadelphia County Medical

Society further data used on an analysis of sixty-four such cases. An abstract of the paper is contained in the *Polyclinic* for March, and we make the following selections:

All of the patients had consumed, for a considerable period, large quantities of the cakes containing the lead chromate, and all showed unmistakable signs of plumbism, which diligent inquiry was unable to trace to other sources.

Of these sixty-four cases 32.8 % (21) are males and 67.18 % (43) are females.

Five women exhibited symptoms of plumbism during gestation, but none aborted, but all at full term gave birth to living children; one had, however, two convulsions at the termination of the seventh month of pregnancy, believed to be of saturnine origin, though a small amount of albumen was present in the urine. Four of these five infants had convulsions two months after birth, in which two died.

78.21 % (50) of the cases exhibited the saturnine cachexia, displaying an anemic appearance with an earthy-yellow hue to the skin; a sallowness without yellowness was present in the remaining 21.87 % (14). In 10.93 % (7) the skin became intensely yellow at one time or another, notably when colic was present. The dull, anemic, somewhat listless look, associated with a peculiar fulness of the cheeks, of which Oliver speaks, and which is considered by him quite suggestive of plumbism, was noticed in but three cases. Emaciation was present in nearly all who had been affected for several months, and in some was marked.

In a large number neurosthenic symptoms antedated for a considerable period the outbreak of colic, arthralgia, or encephalopathy.

Among the neurosthenic symptoms to be especially noted are: the mental depression, which was a prominent symptom in 54.68 % (35), in several it approached melancholia; marked impairment of memory present in 17.18 % (11); great prostration and weakness, the slightest exertion causing fatigue, present in 54.68 % (35)—the fatigue was especially marked on rising in the morning, and may have been caused in part by obstinate insomnia, with nocturnal restlessness, of which the same number complained; vague neuralgic pains as a portion of the neurosthenia — apart from severe arthralgia — were present in 9.36 % (6).

Colicky pains of all sorts, severe and light, attended by more or less constipation, were present in 76.56 % (49), and 60.93 % (38) exhibited the phenomena of pronounced lead colic. These pains were felt most often about the umbilicus, and following that in frequency about the epigastrium; they were in 53 % (26) of the (49) cases relieved by firm pressure when applied gently, and were accompanied by obstinate constipation in 55.10 % (27); and moderate in 34.68 % (17).

Very obstinate constipation was present in all save one woman, whose bowels could be moved without trouble by mild purgatives, and whose passages were described to exceedingly yellow. All had very severe pains in the knees and ankles, unattended by heat, redness, or swelling in any save one man, who, after a few days, had an attack of acute articular rheumatism as a complication. Violent continuous cephalalgia was present in one woman alone, and was the precursor of convulsions, which appeared on the fifth day.

Paralysis of the extensor muscles of the forearm typical wrist-drop, occurred in only two cases; it was bilateral and seemingly complete.

Headache was present in 73.43 % (47); in 67.18 % (43) it was more or less constant for a considerable period, with exacerbations and remissions, and of sufficient severity to indicate involvement of the deep cranial structures.

Encephalopathy was present in 23.43 % (15); in 17.18 % (11) it was manifested as eclampsia; in two (3.12 %) as delirium; in one as a modification of the delirious form, melancholia with accompanying hallucinations and delusions; and in one as coma. The eclamptic seizures were of epileptiform type, and in 10 of the 11 cases were preceded, for days or weeks, by other manifestations of saturninism, such as cachexia, colic, arthralgia, or severe continuous headache; and in at least five of these they occurred primarily, during or immediately subsequent to an attack of colic and arthralgia. In at least four of the ten excruciating cephalalgia preceded for several days their outbreak.

The gums of 80 % (57) of the 64 showed the "bluc line," and it probably existed also in six of the remaining seven cases, but was not looked for.

It is worthy of note that in the viscera of all of the five fatal cases examined by Drs. Reese and Leffmann lead was found, and in four in notable quantities. It was encountered in large quantities in the liver.

Correspondence.

ANOTHER VIEW OF DENTISTS' PATENTS.

Boston, March 30, 1888.

MR. EDITOR,—There is another view to be had, at least for dentists, of the patent question—that of self-preservation. When a dentist has occasion for some new device he invents it. Then, if struck by its value, or proud of his ingenuity, he describes or shows it to his fellows at one of the numerous society meetings, and gets it into the dental magazines, either through a report of the meeting, or perhaps by a communication from himself. One would think this to be a sufficient publication, but it is not. A patent sharp sees the description, rushes off to the patent office and swears out a patent to himself. A company is then formed to handle it, and the whole body of dentists are at once laid under contribution. Individuals cannot fight a moneyed corporation, so, after some recalcitration, they are obliged to submit.

Something like this is the history of the now defunct Cummings' patent, through which the dentists were bled so many thousand dollars; so, also, of the Sheffield Crown patents, and of some others that are now being put upon the market. The result is that the honest man must submit to be fleeced if he uses the invention, or, if not, to throw it into the hands of conscienceless quacks, who see only the money in it.

Therefore, if you have a valuable device which you wish to give to the profession for the good of humanity, the only safety seems to lie in patenting it, else some "combine" will be sure to seize it, and our laws give us but an empty show of a remedy in the courts.

Yours truly, THOS. H. CHANDLER.

REPORTED MORTALITY FOR THE WEEK ENDING MARCH 24, 1888.

Deaths reported 2,443: under five years of age 869; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhæal diseases, whooping-cough, erysipelas and fevers) 343, acute lung diseases 138, consumption 344, diphtheria and croup 128, scarlet fever 45, typhoid fever 38, measles 32, diarrhæal diseases 31, whooping-cough 23, erysipelas 15, malarial fever 11, cerebro-spinal meningitis 10, puerperal fever seven, small-pox New York three. From measles, District of Columbia 18, Baltimore eight, New York and Pittsburgh three each, Boston and Milwaukee one each. From diarrhæal diseases New York 11, Philadelphia five, Baltimore and New Orleans four each, Boston two, Pittsburgh, Milwaukee, Nashville, Fall River and Northampton one each. From whooping-cough New York 13, Baltimore six, Boston, New Orleans, Nashville and Haverhill one each. From erysipelas, New York nine, District of Columbia, Milwaukee, Worcester, Fall River, Lawrence and Salem one each. From malarial fever New York and Baltimore four each, Philadelphia, New Orleans and Charleston one each. From cerebro-spinal meningitis, Milwaukee and Somerville two each, New York, Philadelphia, District of Columbia, Pittsburgh, Worcester and Fall River one each. From puerperal fever, New York three, District of Columbia, Nashville, New Bedford and Malden one each.

In 22 cities and greater towns of Massachusetts with an estimated population of 1,083,650, the total death-rate for the week was 21.01 against 22.58 and 24.37 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending March 10th, the death-rate was 23.3. Deaths reported 4,163; infants under one year of age 949; whooping-cough 165, scarlet fever 59, measles 49, diarrhæa 43, fevers 41, small-pox (Sheffield 28, Manchester and Blackburn two each, Oldham three, Nottingham one) 39.

The death-rates ranged from 15.0 in Halifax to 31.3 in Manchester; Birmingham 22.1; Bradford 17.7; Hull 20.4; Leeds 22.6; Leicester 26.3; Liverpool 27.1; London 23.0; Newcastle-on-Tyne 18.1; Nottingham 20.3; Sheffield 25.5; Sunderland 17.4.

In Edinburgh 18.9; Glasgow 29.5; Dublin 33.1.

The meteorological record for the week ending March 24, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 24, 1888, TO MARCH 30, 1888.

SPENCER, WM. C., major and surgeon. Died March 22, 1888, at Fort Trumbull, Conn.

KIMBALL, J. P., major and surgeon. Granted leave of absence for two months, to take effect about April 10, 1888. S. O. 68, A. G. O., March 23, 1888.

CROSBY, W. D., first lieutenant and assistant surgeon. Granted leave of absence for two weeks. S. O. 29, Department of the Arizona, March 16, 1888.

AZPILL, THOMAS F., captain and assistant surgeon, (retired). Died March 12, 1887, at Fort Lee, N. J.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE met at 19 Boylston Place, on Wednesday, April 11th, at 7.45 o'clock. Papers: Dr. R. W. Lovett, "Sixty Cases of Cerebral Paralysis in Children." Drs. Webber, J. J. Putnam, Rotch, Bradford, Bullard, Hooper, Burrell and E. Reynolds will take part in the discussion. Dr. P. C. Knapp, "Physical Examination of the Stomach in Gastric Disease." Dr. Dr. H. Osgood, "Inveterate Headache."

A. L. MASON, M.D., *Chairman*.

ALEFET N. BLODGETT, M.D., *Secretary*.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—A Regular Meeting of the Society will be held Monday, April 9th, at the Medical Library, 19 Boylston Place. Election of Members. Reader: Dr. E. H. Bradford. Subject: "The Treatment of Lateral Curvature." Dr. John Hounsar will report a "Case of Nephrectomy," and will show the kidney removed from the right loin.

F. B. HARRINGTON, M.D., *Secretary*.

GYNÆCOLOGICAL SOCIETY OF BOSTON.—The next meeting of the Society will be held at the Medical Library Rooms, No. 19 Boylston Place, on Thursday, April 12th, at 4 o'clock, P. M. Papers: "Specialists and Specialists," by Dr. W. Symington Brown. "An Acid Solution of Corrosive Sublimite for Surgical Uses," by Dr. Geo. W. Nash.

H. J. HARRIMAN, M.D., *Secretary*.

APPOINTMENT.

Nicholas Senn, M.D., of Milwaukee, has been appointed Professor of the Principles of Surgery and Surgical Pathology in the Rush Medical College of Chicago.

BOOKS AND PAMPHLETS RECEIVED.

Atlas of Venereal and Skin Diseases, with Original Text. By Prince A. Morrow, A.M., M.D. Fasciculus III. New York: William Wood & Co. 1888.

Essentials of Chemistry and Toxicology: For the Use of Students in Medicine. By R. A. Withams, A.M., M.D. Second edition. New York: William Wood & Co. 1888.

A Biological Examination of the Water Supply of Newton, Mass. By W. T. Sedgwick, Ph.D., and S. R. Bartlett, S.B.

New York Cancer Hospital. Second and Third Annual Report. 1886-1887.

Sixteenth Annual Report of the Board of Health of the City of Boston, for the Year 1887.

The Forty-Ninth Annual Report of the Superintendent of the Boston Lunatic Hospital, to the Board of Directors for Public Institutions, for the Year 1887.

Chroule (Simple) Glaucoma. D. Coggin, M.D., Salem, Mass. Reprint. 1888.

Natural History of Tuberculosis in Accordance with the Germ Theory. By Noah Cressy, M.D., V.S., Ph.D. 1888.

Essays on Hysteria, Brain Tumor, and Some other Cases of Nervous Disease. By Mary Putnam Jacoby, M.D. New York and London: G. P. Putnam's Sons. 1888.

Lecture.

CARTWRIGHT LECTURES.¹
THE GENERAL PATHOLOGY OF FEVER.BY WILLIAM H. WELCH, M.D.,
Professor of Pathology, Johns Hopkins University, Baltimore.

LECTURE II.

THE EFFECTS OF INCREASED TEMPERATURE OF THE BODY.

IN the last lecture I endeavored to bring before you the main facts which we possess bearing upon the explanation of febrile rise of temperature. After a review of our knowledge concerning heat-production, heat-dissipation and heat-regulation in fever, we were led to the conclusion that neither the changes hitherto observed in the production of heat, nor those in the loss of heat, suffice to explain febrile temperatures. Such an explanation seemed possible only upon the assumption that the fever-producing agents act either directly or indirectly upon the nervous mechanism controlling the relations to each other of the production and the discharge of heat. We then turned our attention to the relations of the nervous system to these processes, and found that the investigations of recent years have enabled us to obtain a much clearer conception than was formerly possible of the manner in which the complicated heat-relations in fever may be brought about by an action upon the nervous system. We found even substantial experimental basis in support of clinical facts which show that circumscribed lesions of certain parts of the central nervous system may induce directly febrile disturbances of animal heat.

To carry the subject further, to consider whether pyrogenic agents act primarily or only secondarily upon the processes concerned in heat-production, or upon those concerned in heat-dissipation, or upon the apparatus regulating the relations to each other of these two sets of processes, to discuss whether these agents act directly upon the central nervous system, and, if so, upon what part, or upon the peripheral nerves or their terminations, or upon the tissues, to follow out more fully than we have done hitherto the themes here suggested would lead us, with our present knowledge, into a sea of speculation. We should find only here and there a faint light of fact to guide us. Even upon foundations as insecure as this speculation have their legitimate uses. A good hypothesis is a most valuable incentive to scientific work. It is not my purpose, however, to carry you with me further in this direction, although I realize that a single lecture has been far from sufficient for a satisfactory exposition of the subject.

After dismissing the considerations bearing upon the so-called theory of fever, there still remain a host of questions properly belonging to our subject. It is evidently impossible, even if it were desirable, that these lectures should include a discussion of all of these questions. I have, therefore, selected certain ones, partly because they seem to me of immediate interest, and partly because I have given some attention to their study.

In the present lecture I wish to present to you some observations concerning the relation of elevation of

temperature to other disorders of fever, and as to the question how far increased temperature is a source of danger in fevers.

Here I may repeat that the word fever is used as a convenient name for a group of symptoms commonly associated together in febrile diseases. The association of these symptoms, however, is so loose that we regard only the dominant one, the increased temperature, as the essential criterion of the existence of fever. It saves circumlocution to adopt this somewhat vague and common signification of the term fever, although I think it would be an improvement to confine the term to abnormal elevation of temperature. The literature of fever is full of misapprehensions resulting from the various meanings attached to the word by different authors.

All of the bodily functions may be disordered in fevers. The various symptoms, or classes of symptoms, which are so commonly associated as to be regarded by many as belonging to the febrile processes are, in addition to heightened temperature, increased frequency of the pulse and other circulatory disturbances, increased rapidity of respiration, muscular weakness, lessened secretions, disordered nutrition and digestion, and nervous symptoms.

What is the connection, if any, between these symptoms and the elevation of temperature? What degrees of elevated temperature are dangerous to life, and in what does the danger consist? This subject can at least claim the interest that attaches to the questions of the day. The various opinions which have been held by clinicians on these points are too well known to you to require an historical review. I need only remind you that until within a few years the views advocated with especial force for nearly thirty years by Liebermeister have prevailed, although not without considerable opposition. According to these views the chief source of danger in uncomplicated essential fevers is the elevation of temperature, and the main indication for treatment is the reduction of temperature. Above all it was urged with apparently convincing arguments that the weakness of the heart, which is undoubtedly one of the gravest dangers of fevers, is the direct effect of prolonged high temperature, and is manifested anatomically by parenchymatous or fatty degeneration of the cardiac muscle. Liebermeister sharply defined his position when he said: "A man whose temperature measures continuously 104° (40° C.) or more, surely dies in consequence of the elevation of temperature, one in a few days, another after a somewhat longer time, according to the resistance of the individual." "If his temperature reaches 108.5° (42.5° C.) or more, then he is irreversibly lost."²

At the present moment there is a decided reaction against these views, a reaction which, in some quarters, goes to the extent not only of denying that there is danger in febrile temperatures which do not exceed a very high point, but of asserting that the elevation of temperature is a beneficent provision, a most important vis medicatrix nature, which should not be checked by the interference of the physician. This reaction of opinion is plainly due in great part to the disappointment which has followed the high hopes raised by the discovery of a number of drugs which are admirable antithermic agents, and, nevertheless, do not exert over febrile diseases that controlling influence which had been anticipated.

¹ Delivered at the College of Physicians and Surgeons, New York, April 5, 1888.

² Liebermeister. *Volkman's Sammlung*, No. 31, p. 540.

These questions, you may say, are clinical ones and not much edification is to be expected from their discussion by a pathologist. So far as the propriety of the use of antipyretic agents or of any other mode of treatment in fever is concerned, it is true that the decision must be reached at the bedside and cannot and never should be controlled by the results of experimental pathology. But an appeal has properly been made to experimental pathology to shed light upon such questions as the effects of heat upon the functions of the whole body and of its various organs and upon the causes of parenchymatous and fatty degenerations. The arguments advanced in support of the view that all of the characteristic symptoms of fever are directly dependent upon the increase of temperature and that high temperature is the chief source of danger are derived no less from experimental pathology than from clinical observations.

Three methods have been employed to determine the effects of increased temperature in fever: one is to study the effects of heat upon animals; the second is to examine in different fevers and in different cases of the same fever the relation of the temperature to the other symptoms and to the general condition of the patient; and the third is to note the influence of reduction of temperature upon these symptoms.

Each method has its limitations. The condition produced by exposure to external heat, even if it be called thermic fever, is something quite different from ordinary fevers, and we cannot transfer the results obtained by this method directly to the explanation of febrile phenomena. On the other hand, in the clinical study of fevers it is very difficult and often an arbitrary matter to separate the effects of increased temperature from those of other factors nearly always present. Hence we find no agreement of opinion among physicians as to what symptoms or lesions in fever are referable to the heightened temperature and what are due to infectious or other conditions often present. Even the frequent or constant association of certain symptoms with elevated temperatures and their subsidence or disappearance by reduction of temperature do not justify us in inferring that the high temperature is the cause of the symptoms, for both may be coordinate effects of the same cause, and the so-called antipyretic treatment may influence other conditions as well as the temperature. As has been frequently said of late, the high temperature may be rather an index of the severity of the disease than a source of danger in itself.³

The most direct way of determining the influence of heat upon the body is to raise the internal temperature by external application of heat. Here we are not disturbed by the presence of other factors, such as infection, which render doubtful so many of the conclusions derived from clinical observations as to the effects of high temperature. For the solution of many problems it is evidently irrelevant whether the source of heat be within or without the body. These experiments, if properly conducted, are calculated to shed

much light upon many questions relating to the effects of febrile temperatures.

According to the testimony of all experimenters, a mammalian animal artificially heated dies when its internal temperature reached 111.2° (44° C.) — 113° (45° C.) Death is preceded by convulsions and immediately or soon after death rigor mortis appears. At the moment of death the irritability of the heart and muscles ceases. Death seems to be due to heart paralysis, and the cause of this is usually set down as heat rigor, but this is not probable, as death generally occurs at a temperature several degrees below that at which rigor of the heart-muscles appears.

It is generally agreed that temperature several degrees below those which are fatal must exert toxic effects, and this conclusion seemed to be substantiated by the majority of experimenters who found that animals whose temperatures were artificially raised to 105° (40.6° C.) — 107° (41.7° C.) or even to a lower point manifested signs of illness. These latter results, however, are opposed by those obtained by Rosenthal and especially by Naunyn,⁴ who points out the conditions in most previous experiments were not favorable, as the animals were generally placed in small, dark, poorly ventilated metallic boxes. Naunyn succeeded in keeping a rabbit alive for thirteen days with an average temperature of 106.7° (41.5°).

Following Naunyn's example, I have had constructed a wooden box three feet long, two feet high, and two feet broad, which fits closely within a doubled-walled galvanized iron box. The wooden box is provided with a perforated, movable bottom which allows the urine to escape. The space between the two walls of the iron box measures three inches across and is filled with water which, therefore, surrounds the inner box on all sides, except at the top, which is left open. The dimensions of this apparatus are somewhat larger than those of Naunyn's heating box. A folded woolen blanket was drawn over each end of the box so as to leave uncovered at least one-third and generally more of the top. A rose burner, placed underneath, served to heat the box. At first a thermo-regulator was employed, but this was found unnecessary as the temperature of the room varied but little and there was no difficulty in keeping a sufficiently constant temperature in the box. The experiments were made upon rabbits and only a single one was placed in the box at a time. Corrected thermometers were used. The temperature of the box was taken a short distance above the bottom, and that of the rabbit at a depth of three to four inches in the rectum. This occasion does not seem an appropriate one to describe these experiments in detail with their protocols. I shall take another opportunity for that, and at present give only a general account of those results which relate to the subject before us.

In the box described I have succeeded in keeping for three weeks two large black rabbits, the one with an average rectal temperature of 107.3° (41.8° C.), the other with an average temperature of 106.6° (41.4° C.). The rectal temperature fluctuated usually between 105.5° (40.8° C.) and 108° (42.2° C.), scarcely ever sinking below 105° (40.5° C.), but occasionally rising as high as 109.5° (43.1° C.). The

³In hyperpyrexia and in many cases of insulation there can be no doubt that the high temperature as such are the main elements of danger. But both of these conditions have important points of distinction from ordinary febrile processes. In hyperpyrexia there is probably almost complete paralysis of heat regulation, and we shall find that an analogous condition with similar dangers sometimes develops in animals artificially heated. The cases of insulation in which the high temperature is so dangerous are analogous to the condition which may be produced in animals by brusque elevation of the bodily temperature through exposure to heat and which differs from that resulting from more gradual increase of temperature.

⁴Rosenthal. Zur Kenntniss d. Warmeregulirung u. s. w. Erlangen, 1872.
Naunyn. Archiv. f. exp. Path. u. Pharm., Bd. 18.

temperature of the box varied between 96° (35.5° C.) and 106° (41.1° C.). The rabbits lay most of the time stretched out, breathing very rapidly. They took their food greedily and did not appear ill. At the end of the experiment the first animal was removed from the box and, appearing perfectly well for ten days afterward, it was used for another experiment; the second animal was killed at the end of the experiment and presented marked fatty degeneration of the heart, liver and kidneys. Both animals lost weight while in the box.

In these and similar experiments, the rabbits were given only moist, green fodder, and were allowed to drink plenty of water, which they took eagerly. It is important for the success of the experiment that the temperature should be gradually and not suddenly raised.

Different animals offer varying degrees of resistance to the effects of high external temperatures. It has seemed to me that black and gray rabbits surpass in this respect white rabbits. The same temperature of the box does not produce in all cases the same rectal temperature in different animals, or in the same animal at different times. No factor is of more importance in determining the effects of external heat than the animal's power of temperature regulation. Failure of this power is manifested by a sudden rise of internal temperature which may quickly attain a point incompatible with life. This event may take place without any alteration in the box temperature. The degree of internal temperature at which this paralysis of heat-regulation occurs, varies in different animals. One may be able to hold his temperature from further rise at as high a point as 109.5° (43.1° C.), in another after the temperature has reached 107.6° (41.5° C.), there may occur, without any change in the box temperature, a sudden and often fatal elevation of temperature. In general, temperatures between 108° (42.2° C.), and 109° (42.8° C.), may be regarded as critical temperatures for these animals. One is forcibly reminded by these sudden and dangerous elevation of temperature of the occurrence of hyperpyrexia in certain fevers of human beings, and there is reason to believe that this, too, is caused by paralysis of heat-regulation.

It seemed to me of some practical interest to determine what effect upon the rabbit's power of resisting high temperature is exerted by exhausting influences, particularly by anemia. For this purpose, rabbits which had been moderately bled and others which had been much used for some other experiments, were placed in the hot box. It was found that these animals are, although not without occasional exceptions, unmistakably less resistant to the effects of high temperatures than are robust animals. They succumb sooner, and at lower box temperatures.

We may now consider what inferences may be drawn from these and similar experiments as to the effects of high temperatures. It seems clear that a considerable part of the current arguments based upon experiments concerning the injurious effects of high temperatures, must be revised in the light of Naunyn's experiments and of those which I have briefly related. Because an animal may be killed by raising its temperature to 111° (43.9° C.) or 113° (45° C.), it does not follow that an increase of temperature of four or five degrees above the normal involves danger to life or even any serious disturbance of the functions of

the body. Although experiments in hot air chambers show that in man brusque elevations of the temperature by only a few degrees give rise to serious symptoms. Krishaber⁴ found that by habituation his temperature could be raised to 106.5° (41.4° C.) to 107.2° (41.8° C.), without much discomfort. As small animals generally succumb more readily than large ones to artificial heating, it is not likely that the power of resistance in human beings is less than that found to exist in rabbits, and there is reason to believe that it is greater.

We cannot transfer directly to human beings the highest temperatures at which we found rabbits can exist without serious discomfort, save increased respiration. A rabbit's temperature is normally considerably higher than that of man, and apparently slight causes suffice to produce marked fluctuations. The normal rectal temperature of the rabbits used in my experiments was generally between 102° (38.9° C.), and 103° (39.4° C.). The highest average temperature at which a rabbit was kept for three weeks in the hot box, exceeded, therefore, by four to five degrees F., the average normal temperature. Such an increase would not correspond to a high febrile temperature in man. We can, however, with equal and probably greater propriety, compare this temperature with that at which death surely occurs in a condition bordering on heat rigor. This temperature (111° to 113°), is probably about the same for man as for rabbits and other mammals. From this point of view the inference may be drawn, although of course with much reserve, that human beings may tolerate temperatures of 107° (41.7° C.), or even higher for a considerable time. This inference is supported by clinical observations, especially in cases of relapsing fever.

As already pointed out, the condition produced by artificial heating is not directly comparable with that in fever. In the former, the loss of heat from the body is reduced to a minimum: the superficial temperature is three or more degrees higher than the internal, so that the average temperature of the whole body is higher than in fever with the same internal temperature. We cannot say, therefore, but that man may tolerate considerably higher internal temperatures than when the elevation is brought about under conditions in which the discharge of heat is not checked, than when the temperature is forced up by stopping heat-dissipation. This would be proven if confidence could be placed in the enormous elevation of temperature reported by Teale and others. In these cases, however, even if authenticated, it is probable that heat is abnormally distributed in the body, and we cannot infer that the internal temperature is uniformly raised to such paradoxical heights.

It is of the utmost importance to bear in mind that, as my experiments have shown, not only do animals differ in their power of tolerating high temperatures of the body, but this resistance may be weakened by various depressing causes. Nothing would be more irrational than to conclude that because one individual in a certain condition can tolerate very high temperatures, another in a different condition possesses the same power. In fevers we have various factors, particularly infection, which we may well believe can lower the tolerance of high temperatures. That in some fevers, particularly relapsing fever, this does not appear, or only partially, does not disprove that in

⁴ Krishaber, *Gaz. Méd. de Paris*. 1877.

another fever, such as typhoid or pneumonia, the system may be placed by other factors of the disease in such a condition that even moderately high temperatures are injurious. It does not seem to me proper in these cases to lay, as some seem inclined to do, the sole stress upon the element of infection. This is, in all likelihood, the determining factor, but the practitioner cannot shut his eyes to the possibility that under its influence the high temperature as such, is a source of danger to his patient.

With these restrictions I shall surely not be misunderstood when I assert that temperatures which are ranked as high febrile temperatures do not in themselves, independently of other factors, exert any such injurious influence as has been usually attributed to them.

Our attention up to this point has been directed to the effects of high temperatures upon the general condition of the body. It is of importance for the proper understanding of fever, to determine the influence of heat upon the structure and functions of the various organs. To what extent can the febrile disorders of respiration, of circulation, of secretion, of nutrition, of innervation, be attributed directly to the elevated temperature? These are questions which can be answered better by experimental methods than by clinical observation, for the latter has to deal with the effects of heat complicated by other circumstances whose influence cannot be accurately determined. The one method, however, should be made to control the other.

The most striking immediate effect of heat upon an animal is increased frequency of respiration. When a dog or a rabbit is placed in an atmosphere of 100° (37.5° C.), it at once begins to pant, and the respirations may run up to 150 or more. The causation of this increased respiration, to which the name heat-dyspnoea has been applied by Ackermann,⁶ has been repeatedly investigated. Goldstein,⁷ in Fick's laboratory, found that by applying to the carotid arteries tubes through which hot water is flowing, the respirations may be greatly increased in frequency. Goldstein's experiment is usually cited as the crucial one, showing that the increased breathing is due to the effect of the heated blood upon the respiratory centres in the medulla oblongata. Sihler,⁸ working in the Biological Laboratory of the Johns Hopkins University, however, has demonstrated that the increased respiration of an animal exposed to heat is due to two causes, warmed blood and stimulation of the skin by the heat, and that probably skin-stimulation is the more important factor. Some of Sihler's criticisms of Goldstein's experiments have been met by Gad and Von Mertschinsky,⁹ who have made it evident that increased temperature of the blood stimulates the respiratory centres, or increases their irritability. Section of the vagi does not check heat-dyspnoea, so that this does not result primarily from the action of the increased temperature upon the terminal pulmonary expansion of these nerves. The removal of afferent impulses from the skin by section of the spinal cord does, however, exert so marked an influence that it cannot be doubted that heat-stimulation of the skin is

an important element in the causation. I have convinced myself of the correctness of Sihler's explanation by observing that in the hot-box at temperatures of 90° (32.2° C.), 95° (35° C.), rabbits often preserve their normal temperature, and still their breathing is markedly increased; and that, on the other hand, upon taking them out of the box, the respirations may sink before the internal temperature begins to fall. In one striking experiment, the respirations fell immediately to about normal upon removing from the hot-box a rabbit whose skull had been trephined on each side of the median line, and the optic thalami punctured with a needle.

We cannot transfer directly to human beings the results of experiments on heat-dyspnoea in animals, because in the latter respiration has a far more important function in temperature-regulation than in the former. To keep cool, a dog pants under circumstances when a man sweats. As heat-regulation is largely influenced by the cutaneous temperature, it is not improbable that in man heat-stimulation of the skin is less prominent than the warmed blood acting upon the respiratory centres in increasing the frequency of respiration in fever.

Inasmuch as disturbances of the heart and of the circulation in general are among the most important symptoms of fever, it is natural that much attention should have been given to the study of the effects of heat upon the organs of circulation. The supposed injurious effects of prolonged high temperatures in fever have been usually attributed especially to some toxic action of heat upon the heart.

That the pulse-rate is quickened by artificially heating rabbits and dogs has long been known. The positive demonstration that this acceleration is due to the direct action of the heated blood upon the mammalian heart itself was first given by my colleague, Professor Martin.¹⁰ By conducting through the dog's heart, isolated physiologically by the ingenious method which he devised, Martin proved that the heart "beats quicker when supplied with warm blood, and slower when cold blood is supplied to it; also, that the rate of beat depends much more upon the temperature of the blood in the coronary arteries than on its temperature in the right auricle or ventricle." These experiments make it unnecessary to recur to any action of the heated blood upon extrinsic cardiac nerves or nerve-centres in order to explain the quickened pulse of fever. Moreover, Fick¹¹ found that the nervous centres of the heart and bloodvessels are unaffected by heating the blood flowing through the carotid arteries in the manner adopted by Goldstein in his experiments on heat-dyspnoea.

Professor Martin has kindly permitted me, in this connection, to mention certain unpublished results of experiments which he is now conducting upon the effects of heat and cold on the isolated heart. As these results are pertinent to our subject, I gladly avail myself of this privilege. The table of an experiment which I have examined shows that the isolated cat's heart beats regularly and more and more rapidly as the temperature of the blood is gradually raised to 111.2° (44° C.). At this point the beats become irregular, but are restored to their normal rhythm by feeding the heart with cooler blood. The temperature of

¹¹ Fick. *Plüger's Archiv*, Bd. V.

about 111° (43.9° C.) appears to be a critical one for the isolated heart. Above 111.2° (44° C.) to 113° (45° C.), the pulsations become slower, instead of quicker, as the temperature is raised. At 122° (50° C.) the heart's action ceased, but it was made to beat again by supplying it with cooler blood, showing that the cessation was not due to heat-rigor. This interesting experiment teaches, among other things, that very high temperatures may produce results differing not only in degree, but also in kind, from those of temperatures only a degree or two lower.

We may consider it, then, established that increased frequency of the pulse in fever is referable to the direct action of the warmer blood on the nervo-muscular substance of the heart itself. Clinical observation of cases of fever makes it evident that there may be and often are present other circumstances which influence the rapidity of the heart's pulsations—circumstances which, in themselves, may slow or may quicken the pulse. Large series of statistics, therefore, are required to bring out the ratio between the pulse-rate and the temperature in fever, and even then, for any given temperature, the maximum and the minimum pulse-rates lie so far apart that the statement of the average increase in the frequency of the pulse for each degree of rise of temperature, such as has been computed by Liebermeister, has very little value.

Not only is the pulse-rate quickened in fever, but there are often other and more serious circulatory disturbances. In the fever produced in rabbits by the injection of the swine-plague bacillus I find a reduction of the blood-pressure measured in the carotid artery, and others have obtained similar results in the artificial fevers of animals. The determination of the blood-pressure in fevers of human beings by means of Basch's sphygmomanometer has given, in the hands of different experimenters, such contradictory results that no conclusion can be drawn, unless it be the very probable one that the blood-pressure varies, being sometimes high, sometimes low, and sometimes normal in fever. That the arterial tension is often reduced is made evident by the marked diastolic of the pulse wave. This diastolic, however, characterizes particularly septic and typhoid types of fever, and is absent during the chill of intermittent fever, and often in exanthematous and some other fevers, so that we cannot consider the blood-pressure and arterial tension as having any such definite relation to fever as does the pulse-rate.

It has been observed by Paschutin, Senator and Mendelson¹² that the blood-pressure rises with increased bodily temperature produced by exposure to heat. Mendelson found that the pressure begins to sink as the temperature approaches a point incompatible with life. In these experiments the animals were subjected to rapid elevations of temperature. I find that when a rabbit is gradually and cautiously heated in the hot box used in my experiments the rise of temperature is less marked, and may not surpass even for temperatures of 107° (41.7° C.) the normal limits of variation which may be found in the blood-pressure of the same animal examined at different times. These measurements, however, are not very conclusive, for, as has been already remarked, rabbits which have

been operated upon do not stand well artificial heating.

I have observed that the rhythmical contractions of the bloodvessels of the rabbit's ear are feeble or absent when the temperature is much elevated by artificial heating, whereas it will be remembered that in experimental septic fever these contractions are irregular and exaggerated.

Upon the whole I think that we are justified in concluding that the variations of arterial tension in fever are much less dependent upon increased temperature than upon other factors, such as infection.

But the cornerstone of the doctrines which teaches that a chief source of danger in fever is the elevation of temperature is not the effect of increased temperature upon the pulse-rate or the arterial pressure, but is the belief that prolonged high temperature exerts a directly paralyzing influence upon the heart. The main support of this belief is not the admitted fact that extremely high temperatures paralyze the heart, for these critical temperatures lie far above the ordinary high temperatures of fever, and in a region where all admit the dangers of the excessive internal heat. The stately superstructure has been built up chiefly on the basis of experiments showing that when the internal temperature of animals has been maintained for some time at a high point by exposure to external heat, parenchymatous, or fatty degeneration of the heart-muscle, ensues. It is true that all experiments are not in accord upon this point, and that, as a rule, pathological anatomists have not given adherence to the doctrine that parenchymatous degenerations are chiefly dependent upon high temperature, still this doctrine has gained a wide acceptance among clinical men, and is advocated with especial force by Liebermeister. I have, therefore, thought it desirable in my experiments to give especial attention to this question.

Among previous experimenters on artificial heating of animals Iwaschkewitsch, Wickham Legg, and Litten were most successful as finding parenchymatous, or fatty degeneration of the heart, liver and kidneys, and Walther, Obeynier, and Naunyn, as obtaining only negative results. It is not necessary here to enter into a criticism of these different experiments, which are of very unequal value. Litten's¹³ experiments, on the one side, and Naunyn's¹⁴ on the other, appear to be the most carefully conducted. Litten, whose experiments are those usually cited, kept guinea-pigs in a double-walled metallic box, which was at a constant temperature of 98.8° (37° C.) with dry air, or of 96.6° (36.6° C.) with moist air. He never failed to find fatty degeneration at the end of thirty-six to forty-eight hours. The liver was first affected, and then the heart and kidneys, which became fatty by the second or third day. The animals did not survive longer than five or six days, and by that time the fatty degenerations had reached an extreme degree. Von Recklinghausen¹⁵ urges, with apparent justice, against these experiments, that the enforced inactivity of the muscles, and the imperfect ventilation, may have had as much to do in causing the degenerations as had the high temperature. These objections find support in the experiments of Naunyn, who making use of a much larger and better ventilat-

ing heating-box than Litten, failed to find any parenchymatous or fatty degeneration in his rabbits after they had been exposed for two weeks to higher temperatures than Litten employed.

As my experiments confirmed in other respects Nannyn's results, I was quite unprepared to find that my rabbits, after a variable period of artificial heating, quite constantly presented fatty degeneration of the heart, liver and kidneys, and sometimes of the diaphragmatic and intercostal muscles. I never found the degeneration at so early a period as did Litten. It was not until the rabbit had been kept for at least a week, with an average rectal temperature of 107° (41.1° C.), that the degeneration was noticed, and then only in moderate degree. The higher and the less fluctuating the internal temperature the more certain was the degeneration to appear. I could reckon upon obtaining rabbits with well-marked fatty degeneration of the heart by keeping them for ten days with a rectal temperature between 107° (41.7° C.) and 108° (42.2° C.). I am not prepared to account for the discrepancy in this respect between Nannyn's and my experiments. The box used was larger than that employed by him, and every care was taken to keep it well ventilated by leaving at least one-third, and often one-half, of the top open.

I do not think that my experiments altogether do away with the force of Von Recklinghausen's criticisms. The fact that in these experiments the degeneration made its appearance at the end of a week or ten days, and in Litten's in forty-eight hours, to say nothing of Wickham Legg finding it at the end of twelve hours, would suggest that if the rabbits were heated in a still larger and better ventilated apartment, the degeneration might not occur at all, or might be deferred to a much later period. In my opinion, however, even if full allowance be made for this line of argument, we must still admit that prolonged high temperature is an important factor in the causation of fatty degeneration.

That it is not the sole factor, no one can doubt. As is well known, fatty degeneration is produced by anemia and by a variety of poisons, and even in fevers, most pathologists are convinced that it bears a closer relation to the kind and the degree of infection than it does to the height of the temperature. It is more frequently absent than present in pneumonia, even where there have been symptoms of heart failure.

The kind of degeneration present in my rabbits was fatty, and not parenchymatous. Probably all who make many post-mortem examinations will agree with Von Recklinghausen that altogether too liberal use has been made of the diagnosis of parenchymatous degeneration, and not sufficient account has been taken of the anatomical changes of the parenchyma produced by post-mortem chemical changes, such as acid formation, etc.

In order to determine what influence is exerted by infection combined with high temperature, I inoculated a rabbit which had been in the hot box for four days with the bacilli of swine plague. These bacilli, if not identical with, are closely allied to those of rabbit septicaemia, and are extraordinarily virulent for rabbits. In thirty-six hours the animal, which had remained at a high temperature in the box, was dead, and the most extreme fatty degeneration of the heart and other organs was found. As in other experiments, the degeneration had not made its appearance

at this early date, there can be no doubt that the infection was an important element in the causation. That it received powerful support in the high temperature, however, is proven by the fact that little or no degeneration of the heart is observed after infection with this organism when the animal is kept at ordinary temperatures.

Admitting, then, that high temperature aids in the causation of fatty degeneration of the heart in fever, the question arises: what do we know of the effects of this degeneration upon the functions of the heart? I will say nothing of the growing tendency to transfer a large part of the classical symptomatology of Quain's fatty heart to other conditions, particularly to disease of the coronary arteries and chronic myocarditis; we are concerned at present only with the occurrence of this degeneration in fever. Have we not been somewhat hasty in assigning to degenerations of the heart-muscle so large a share in the production of heart-failure in fevers? One cannot look at a muscular fibre in which the striated substance is all replaced by fatty globules, and suppose that its functional activity was unimpaired, but into what serious errors should we fall if we attempted to deduce from the anatomical changes in the liver cells or the renal epithelium the corresponding functional disturbances? Certain it is that symptoms which are usually considered those of heart-failure are often enough present in fevers without finding at the autopsy any degeneration of the heart; and, on the other hand, such degeneration may be discovered without any history of these symptoms, although, of course, the two are often associated.

In the face of these doubts, it seemed desirable to determine, if possible, experimentally the damage inflicted upon the cardiac functions by the presence of fatty degeneration of the heart-muscle. That this degeneration may exist without apparent injury is rendered probable by the fact that a rabbit which has been kept for three weeks in the hot box at a high temperature, and in which there is every reason to suppose that fatty degeneration has occurred, may present no symptoms of heart-paralysis, and when removed from the box, appear and remain perfectly normal. An instance has already been mentioned, where one rabbit at the end of three weeks was killed, and presented marked fatty degeneration of the heart; and another, which had possessed a higher average rectal temperature, was removed from the box at the end of the same period, and appeared for ten days perfectly normal, when it was used for another purpose. That this degeneration can be recovered from is, moreover, rendered probable by clinical experience, and is universally admitted.

Once, in tearing out a bit of fatty heart-muscle from one of the rabbits, I made a curious observation. Near the edge of the cover-glass, where there was a slight current in the physiological salt solution, rhythmic contraction was observed in a group of muscle-fibres. This interesting spectacle could be watched under the microscope for ten minutes. These contracting fibres were filled with fatty globules, and only here and there, and then indistinctly, could any trace of striation be detected. This observation teaches that a fatty, degenerated muscular fibre is capable of contraction, but, of course, warrants no further conclusions.

Far more important than any inferences which can be drawn from such observations is the measurement

of the actual blood-pressure in animals whose hearts have undergone fatty degeneration. This I have done in three instances. The rabbit was removed from the box at the end of ten days to two weeks, and the pressure in the carotid artery was measured by a mercury manometer attached to Ludwig's kymograph. In no instance was the blood-pressure found to be lower than that normally present in rabbits. In an experiment recently performed, the average pressure was 125 mm. of mercury; the pulsations were regular; the heart responded to stimulation of the vagi in an entirely normal manner. After such stimulation, the pressure in one case rose to 176 mm. of mercury. Immediately after the measurement of the blood-pressure, the rabbit, as in the previous instances, was killed, and marked fatty degeneration of the muscular fibres was found. In many of the fibres the striation could not be made out, and only fatty globules were visible; in others, which also contained fatty granules, the striation was distinct. The degeneration involved the whole muscular structure of the heart. A similar appearance in a human heart would be considered to indicate well-marked fatty degeneration.

These experiments show that a rabbit's heart which has undergone marked fatty degeneration from exposure to heat, may perform its functions, to all appearances, and for the time being, in a perfectly normal manner. There is at least one consideration which should make us cautious in drawing far-reaching conclusions from these experiments. There are diseases of the heart, I need only refer to lesions of the coronary arteries, in which the functions of the organ are performed for a longer or shorter time apparently in a perfectly normal way, and then heart-failure suddenly appears. It is probable that here, too, the blood-pressure would be found normal at a certain period of the disease, and still it would be an error to suppose that the lesion does not damage the heart. Whatever force there may be in this analogy, I still think that these experiments as well as careful pathological and clinical observations, necessitates some revision of the current opinions concerning the significance of fatty degeneration of the heart in fever.

So much time has been devoted to a consideration of the effects of heat upon the respiration and the heart, that the limits of the present lecture will permit hardly more than a summary of the effects exerted by heat upon other functions and organs of the body. On account of the great clinical importance of the subject it seemed desirable to treat with especial fullness the influence of increased temperature on the heart.

What part has increased temperature in producing febrile consumption of tissue? In the first lecture mention was made of Pflüger's experiments, showing that animals with elevated temperature produced by exposure to heat, absorb more oxygen and excrete more carbonic acid than at the normal temperature. This is in conformity with the general law that within certain limits cell-activity is more energetic at high than at low temperatures. It was also shown in the first lecture that only a comparatively small part of the increased oxygen absorption and carbonic acid elimination in fever can be referred to the immediate effects of high temperature. It has not been demonstrated that the respiratory gases in human beings are increased by artificial elevation of temperature. In-

deed, Voit¹⁶ was unable to find any such effect of increased temperature in human beings on the respiratory gases as both he and Pflüger observed in animals.

Inasmuch as increased disintegration of nitrogenous material is such a prominent disorder in fever, much attention has naturally been given to determining how far this can be explained by elevated temperature. That it cannot all be so explained is proven by the interesting observation of Sydney Ringer, that excessive elimination of urea antedates the rise of temperature in intermittent fever, and Nauyn has found the same to be true of the septic fever of dogs.

The experiments which have been made to determine the influence of artificial heating on the amount of urea excreted by man and by animals, have yielded contradictory results. A number of these experiments are of little or no value, because no attention was given to establishing beforehand, nitrogen equilibrium. Schleich's¹⁷ experiments may be mentioned as perhaps the most accurate of those showing an increase in the urea excreted under the influence of exposure to heat. The more recent experiments of Simanowsky¹⁸ were made in Voit's laboratory with especial precautions as to the establishment of nitrogen equilibrium. He failed to find any increase in the excretion of urea as the result of exposure to external heat. While then this question must be left at present *sub judice*, there can be no doubt that only a part at least of the excessive disintegration of nitrogenous substance in fever can be assigned to the influence of the increased temperature.

The loss of weight exhibited by animals kept for a long time in a hot atmosphere is usually explained by the excessive evaporation of water from the body. In many of my experiments the rabbits were freely supplied with food and water, and still the loss of weight was very noticeable. I am inclined, therefore, to attribute to the increased temperature under these conditions a decided influence upon the consumption of tissue.

Senator¹⁹ found the urine of rabbits artificially heated to contain more albumen than is found occasionally in the urine of healthy rabbits. This observation I have not been able to confirm on the rabbits in my experiments, and probably this difference is to be explained by the more rapid and intense heating employed in Senator's experiments. Senator explains the heat albuminuria by the rise of arterial pressure in the renal vessels, but this is not in conformity with the interesting experiments of Mendelson,²⁰ who found by means of Roy's oncometer that both in thermic and in septic fevers of dogs the kidney is anæmic, while the general blood-pressure is elevated.

No satisfactory explanation has yet been offered of the diminution of perspiration which distinguishes fever so strikingly from the condition produced by exposure to high external temperatures. Luchsinger's assertion that this is the result of lessened irritability of the sweat-centres in the spinal cord remains to be proven, and at the best is not a satisfying explanation.

Bokai,²¹ in a recent experimental research on intestinal peristalsis in thermic and in septic fevers, comes to the conclusion that the constipation of fever is to be explained by the heated blood stimulating the

²¹ Bokai, Archiv. f. exp. Path. u. Pharm., Bd. 23.

nerves inhibiting intestinal peristalsis. If this should be confirmed, then it would be proven that at least three symptoms of fever, the quickened respiration and pulse and the constipation, are direct effects of elevated temperature.

When we consider the important nutritive changes in the muscle accompanying increased thermogenesis we shall be inclined to attribute to these alterations and the associated abnormal innervation, rather than to increased temperature, the muscular pains and weakness which form such an early and frequent complaint in fevers.

The investigations hitherto published of changes in the blood produced by increased temperature within febrile limits are not of sufficiently definite and satisfactory nature to warrant any consideration on the present occasion.

Nor am I acquainted with any positive experimental evidence (save Bokai's work already mentioned) that increased temperature is concerned in the production of the digestive disorders of fever. It has already been said that the rabbits with high internal temperatures in the hot box ate greedily, but these voracious animals cannot be considered favorable subjects to test this question.

Especial emphasis has been laid by Liebermeister and those who accept his teachings, upon the dependence of the nervous symptoms of fever, particularly the so called typhoid symptoms, on the elevation of temperature. There is, however, abundant clinical evidence to disprove this doctrine. Reference need be made only to relapsing fever, and especially to the aseptic fever described by Genzmer and Volkmann, in which there is entire absence of the whole group of so-called nervous symptoms. Moreover, Liebermeister's opinion in this respect is not supported by adequate experimental evidence. Unless the temperature of the brain or of the entire animal be brusquely raised to a high point by coarse methods no disturbance of the cerebral functions is noticed until the temperature reaches a critical point, beyond which further increase is likely to prove rapidly fatal. At this critical point the animal, which before has lain quietly, becomes very uneasy, and if the temperature rises higher it has convulsions and coma, and dies.

I have endeavored to bring before you in this lecture the experimental evidence relating to the effects of increased temperature upon the general condition of the body, and upon the functions of its various organs. I have given account, as briefly as possible, of some experiments which perhaps shed additional light upon this important subject. In the course of this lecture emphasis has repeatedly been laid upon the necessity of controlling the results of the experimental method by clinical observation, and here and there I have endeavored to institute this control. Further than this I shall not attempt to set before you the clinical evidence regarding the effects of increased temperature in fever. There are those here more competent than I to deal with this side of the question. We may feel assured that when all the facts are before us, and are properly interpreted there can be no lack of harmony between the results of experimental and those of clinical investigations.

FRACTURE OF THE STERNUM, WITH DISLOCATION OF FRAGMENTS; RESTORATION TO PLACE BY TREATMENT BY POSITION; RECOVERY.

BY CHARLES E. PORTER, M.D.,
Professor of Clinical Surgery Harvard Medical School, Surgeon Massachusetts General Hospital.

FRACTURE OF the sternum alone is an extremely rare accident, but as a complication in crushing injuries of the thorax it is associated with fracture of the spine or ribs. At St. George's Hospital in four years nine cases were examined, three associated with fracture of the spine, and six with fractured ribs. Malgaigne recorded but ten cases, five of which ended fatally on account of complications as mentioned above. The causes are usually direct violence, as crushing blows upon the chest, though violent bending of the spine backwards has produced it. "One case (Chevance's) was caused by violent forward flexing of the body from a fall."

Dr. Fagel, of Mexico, reports this accident as having happened to a celebrated vaulter, who whilst bending his body backward, was endeavoring to raise a heavy weight with his teeth. The complications are injury and inflammation of the pericardium, pleura, lungs, mediastinum and heart.

Authorities differ as to treatment advised. Some recommend the recumbent position, with a pad between the scapulae, and head low. Others the sitting posture, with the head thrown back. Others operative measures, as the lifting of the depressed fragment by means of the trephine and elevator, or the corkscrew; while another says that these latter methods are "the relics of the old, cruel and barbarous surgery." It seems to me that after position and manipulation have failed, and deep inflammation threatens, that some operative interference is indicated, and especially if the displaced fragment is pressing upon the trachea, or the large vessels.

The case which I have to report is that of Captain Holden, aged twenty-one, captain of the Harvard football eleven, and I give the name as, at the time of the accident (one of the intercollegiate games), it became generally known through the papers. Captain Holden stood erect ready to tackle one of the opposing team, who was running with the ball. As his opponent reached him he jumped, and his knee struck Holden on the sternum, producing a fracture and dislocation of the upper fragment backwards, the lower one overriding. The point of fracture was at the junction of the second and third pieces of the gladiolus. The ossification at this point is completed between the twentieth and twenty-fifth years of age, so that the separation was of the nature of an epiphysal fracture. There was profound shock and agonizing pain. The depression seemed to be little more than the thickness of the sternum. He was removed to the Massachusetts General Hospital, and in consultation with the other members of the staff it was decided to try the effect of the recumbent position, with hard pad between the shoulder blades, and the head lower than the chest. This position was most painful, and after some hours the pad was removed.

On the next day there was no change in the position, and the patient suffered greatly from pain in the

bowels, which did not yield to cathartics or enemata. He had retention, requiring the catheter. Morphine was given subcutaneously.

On the third day no change. The patient was lifted from the bed to the erect position, and, supported under either arm, was bent backwards as far as possible. This produced a sickening pain at seat of injury, and he feared he would faint, and he was put back to bed. About half an hour afterwards, on coughing and taking a deep respiration, the bone suddenly snapped forward into place. A broad band plaster was immediately applied (such as is used in fracture of the ribs) to hold the chest walls immovable, and compel diaphragmatic respiration. The plaster was changed from time to time, and there was no re-displacement. There was slight cough for ten days. Eleven days after injury he was up, and in three weeks left the hospital. There was no resulting deformity.

DISLOCATION OF THE BONES OF THE STERNUM.

BY C. B. LYMAN, M.D., DENVER, COL.,
Assistant Surgeon, Union Pacific Railroad.

THE patient, a passenger brakeman on the Union Pacific Railroad, was twenty-seven years old. On January 22d, while running up an embankment to catch a train, and when nearly at the top, he fell, and struck with his chest upon the end of a projecting tie. He suffered a good deal of pain during the day, and with every breath or movement of the body, he felt something snap at the seat of pain.

I first saw him on January 25th, three days after the accident; the pain had diminished, but he could still feel the snapping. Upon examination I found a depression of nearly half an inch just below the line of the second ribs, and in the median line; with forced inspiration there was a distinct cartilaginous grating. In fact, I had to do with a backward dislocation of the gladiolus upon the manubrium, the second rib on each side remaining attached to the manubrium.

Reduction was attempted by manipulation of the fragments, and also by standing behind the patient and drawing the shoulders back forcibly, while the patient was made to take a deep inspiration. This, however, failed. The patient was then taken to the Union Pacific Hospital and etherized; the dislocation was then reduced by Dr. O. J. Pierce and myself by depressing the upper fragment firmly, while pressure was being exerted upon the chest in the axillary line on either side, over the ribs which were attached to the lower fragment, the object being to spring the lower fragment forward at the same moment that the upper fragment was most depressed.

This failed several times; but finally, the patient most opportunely gave a slight cough, owing to fresh ether on the sponge, just at the moment when pressure was being exerted as described, and the lower fragment came forward into line with a distinct crepitus. An adhesive strip was then placed around the chest to hold the fragments immobile for a few days. There has been no tendency to re-dislocation, and the fragments remain in perfect line. This case is of interest for several reasons:

(1) On account of the infrequency of the accident. Poland, in "Holmes's System," says that during the

last thirty years "several cases" have been seen at Guy's Hospital.

(2) Its method of production. Most of the cases reported, have been produced by indirect violence; this was produced by direct violence, the end of the tie striking the sternum just below the line between the manubrium and the gladiolus.

(3) Because the lower fragment was displaced backwards. In almost every case on record the upper fragment has been displaced backward instead of the lower one.

RECENT PROGRESS IN PUBLIC HYGIENE.

BY SAMUEL W. ABBOTT, M.D.

THE ACTION OF DIFFERENT WATER-SUPPLIES UPON LEAD-PIPES.¹

SHEFFIELD, in England, has a population of about 300,000. It is supplied with water from several reservoirs, being of moorland origin and furnished by gravity. The high service of the town is furnished from a separate reservoir. Cases of lead-poisoning have been frequent in the town, and there has been an alarming increase of such cases during the past winter, the recent cases amounting to several hundred. On inquiry it was found that these were quite exclusively among the population supplied from the high-service reservoir. The waters of these reservoirs are obtained from different districts; and in the case of the lower-level water the amount of lead per gallon has usually been but a trace only, never more than $\frac{1}{10}$ grain even after standing in the pipes all night, while that in the higher-level water has often been found to be as high as $\frac{1}{2}$ grain per gallon, and occasionally as much as $1\frac{1}{4}$ grains.

The water of the high-service was found to be distinctly acid, and it was claimed that the acid was of vegetable origin, arising from the peat upon the moors.

Certain differences in the character of the supplies may account for the variable action of the water upon lead.

The low-level supply is obtained partly from a reservoir, the water in which has been stored for a long time, and the water of this supply also passes for two miles through a brick conduit, the mortar of which may cause the neutralization of the free acid. These, however, are mere conjectures, since no systematic inquiry has been made. The water company has had blocks of limestone placed in the conduit. Mr. Allen, the public analyst, criticizes this measure, saying that the use of too much limestone will injure the water, and render it as liable to act upon lead as if it had not been thus treated. He says, moreover, that the only rational method of using lime is to introduce it regularly and constantly in powder, or as milk of lime, in such quantity as previous analysis shall have shown to be requisite for the neutralization of the free acid.

The panic produced by this epidemic of lead-poisoning was followed by an alarming waste of water, the taps being kept open for hours at a time. The filter manufacturers drove a lively trade, since it was found that animal charcoal seemed capable of removing lead from the water, probably, as the writer states, in con-

¹ The Sheffield Water-Supply and Lead-poisoning. By Alfred H. Allen, F.C.S. Sanitary Record, Feb. 15, 1888, p. 326.

sequence of the phosphates contained in such charcoal, and the consequent formation of insoluble phosphate of lead.

Mr. Allen further suggests that the present action of the high-service water is not due to its deficiency in silica, since he finds that its proportion of silica is sensibly in excess of the amount claimed by Dr. Tidy, to afford perfect immunity from lead-corrosion.

Dr. Richter reports that about one hundred cases of lead-poisoning occurred in Dessau as a consequence of changing the source of public water-supply. A curious feature of this epidemic was that not a single child was attacked. The quantity of lead present in the water occasionally exceeded seven milligrammes per litre, which had been regarded as a limit of danger. Dr. Richter observed that it was not so much the amount present which harmed, as the long-continued exhibition of small quantities of lead which collect in the body till the point is reached, when the organs can no longer withstand the poison.²

TYPHOID FEVER AS AFFECTED BY THE PUBLIC WATER-SUPPLY OF VIENNA.³

In this paper, by M. Mosny, the oft-repeated observation as to the influence of a pure water-supply in reducing the mortality from typhoid fever receives a new and vigorous confirmation. Other diseases have been diminished in like manner. Not a single death from dysentery has occurred since 1880 in Vienna. The water-supply of Vienna up to 1861 was partly from wells, of which there were then about 10,000 in use, and, as might have been expected, water-pollution was the rule. There were also public and private aqueducts conveying water from the Danube canal, and finally a more thorough public supply from distant springs of undoubted purity.

The prevalence of typhoid fever and, notably the epidemic of 1877 was mainly in the houses not supplied with the public spring-water supply.

In concluding this article the author says, "We conclude that water is the principal agent in the transmission of typhoid fever, and in order to cause this disease almost entirely to disappear from a large city where it is endemic, it is only necessary to furnish to the inhabitants water of unquestionable purity, and in sufficient quantity."

The population supplied from the new sources in Vienna is 761,000, and the consumption per capita 170 litres per day (about 45 gallons).

THE SEWAGE WORKS OF WIESBADEN.⁴

These works are constructed upon a modification of the Frankfort, and of the Rökner-Rothe processes. The sewage is made to part with a large part of its impurities by being passed upward and downward through chambers arranged in front of the tanks. It goes through a previous straining process to remove all floating substances, and is then mixed with the precipitant (milk of lime) in a chamber where a thorough agitation is effected by blowing in air. The sewage then passes over a weir into a narrow chamber, at the bottom of which it is conducted through small openings in the division wall into a second cham-

ber, which it traverses in an upward direction, and then over a second screen wall and down through a third chamber into a fourth, through which it ascends into the depositing tanks, three in number. These can be used together or separately. The total quantity of sewage treated per day is estimated at 6,500 cubic metres.

THE SCHWARTZKOPFF SEWAGE SYSTEM AT EHREN-FELD.

This plan as described by Professor Arnold, of Brunswick, differs from the Liernur system in that the sewage is brought to the outfall by gravitation, and lifted into the apparatus for treatment in the same manner as in the Rökner-Rothe process. A separate system of sewerage is, however, essential.

The sewage flow is conducted into iron reservoirs, from which it is drawn into an exhausted horizontal receiver, furnished with a revolving stirrer, the blades of which tear in pieces all solid matter, and thoroughly churn the sewage. The discharge from this receiver takes place under varying pressures, and the amount of the precipitants is added in proportionate quantities by means of rotary taps, which measure a fixed quantity at each turn, and vary in speed in accordance with the rapidity of flow. The chemicals used are lime, sulphate of magnesia and phosphates, and with these the sewage is agitated and mixed in four circular tanks provided with stirrers.

Up to this point the operations are conducted in closed vessels, a matter of sanitary importance. The chemically-treated sewage passes into an open channel, from which, by means of sluices, it can be turned into any one of three tanks, each capable of holding one-tenth of the day's flow. These are filled in succession, and the sludge sinks to the bottom, while the water becomes clarified in the usual way, the time required being about one hour. By means of taps at different depths the clear liquid can be drawn down to the sludge level. The supernatant liquid passes on to a peat-filter, provided with a grating, and from this is discharged a perfectly clarified effluent, absolutely free from smell. The sludge is let off by a tap into another vessel, where it becomes partially consolidated, but still contains eighty-five to ninety per cent. of water. It is subsequently dried in thin layers, and ultimately mixed with the peat from the filters, and made up by hand into flat cakes, to be used as a fertilizer.⁵

THE MÜLLER-NAHNSEN SYSTEM AT HALLE.⁶

Dr. Blasius refers to the former report on the Rökner-Rothe process at Essen, and to the recommendation that a trial of the same should be made in Brunswick. Owing to favorable accounts of the working of the new system at Halle, it was resolved to send a deputation from Brunswick to study the process on the spot, and advise whether a trial of it should be made. A visit was paid to Halle for this purpose on October 16, 1886. The works, which are substantially built, and of a permanent character, are described. The total cost was 32,000 marks (\$8,000). Samples of the raw sewage and of the effluent water were taken by the author, as also of the pressed sludge, and these, carefully packed and preserved in ice, were brought to Brunswick for analysis. The bacteriological exam-

² Deutsche Vierteljahrsschrift für öffentliche Gesundheitspflege, 1887, page 412.

³ From a communication made to the Society of Public Medicine, Dec. 28, 1877. Revue d'hygiène, Jan., 1888, p. 18.

⁴ Deutsche Vierteljahrsschrift für öffentliche Gesundheitspflege, 1887, p. 81.

⁵ Deutsche Vierteljahrsschrift für öffentliche Gesundheitspflege, 1887, p. 92.

⁶ Monatsblatt für öffentliche Gesundheitspflege, 1887, p. 49.

ination of the raw sewage gave, in two comparative statements, 6,220,800, and 6,825,600 colonies per cubic centimetre, and in the effluent water only 14 and 3 colonies respectively, the former of which in 6, and the latter in 5, days, increased to 150 and 53 respectively. Detailed analyses are given of the sewage water, the effluent, and of the pressed sludge. The result of this treatment was, that the suspended matter was entirely removed; the amount of inorganic substances in solution was slightly decreased, while the fixed organic matters in solution were increased about 25 per cent.; the total amount of organic matters dissolved in the effluent being two-thirds greater than in the raw sewage. The percentage of chlorides was enlarged by one-half, and the phosphoric acid was only partially removed. The nitric acid was nearly doubled, owing to the oxidation of the ammonia, the volume of which was reduced by one-half. The sludge, which when dried at 105 centigrade, contained 82.52 per cent. of inorganic matters, and 17.48 per cent. of organic substances, yielded only 16.72 per cent. of phosphoric acid, the nitrogen being 0.926 per cent. The value of this sludge is given at 30 pfennige the centner (4d per cwt.). Each cubic metre of sewage water yields about one kilogram of pressed sludge. The cost of treatment for 4,501 cubic metres of sewage was 161 marks, 92.80 marks being for chemicals, and 68.20 marks for labor; equivalent to 3.35 pfennige per cubic metre. As compared with the cost of the Röckner-Rothe system, which was shown to be 1.70 pfennige per cubic metre, this system is just twice as dear. But for the Röckner-Rothe system each cubic metre of sewage required the addition of 0.52 kilogram of precipitants, while for the Müller-Nahnsen process only 0.39 kilogram of precipitants is employed. The quantities used being thus, roughly, as 3 to 4, while the relative cost is approximately as 2 to 1. From this it follows that the average cost of chemicals for the Müller-Nahnsen process is 160 per cent. dearer than those for the Röckner-Rothe plan; the results of treatment being slightly in favor of the latter process. A trial therefore at Brunswick was deemed unnecessary.

THE AGE FOR RE-VACCINATION.⁷

The Local Government Board has issued an order dated February 3, 1888, amending former regulations, as to the age at which re-vaccination may be furnished at the public expense. The new order provides that re-vaccination by a public vaccinator may be performed when the applicant has attained the age of twelve years (instead of fifteen years as heretofore), or in case of imminent danger from small-pox, at ten years (instead of twelve as heretofore), and has not before been successfully vaccinated.

The order further provides, with reference to children in public institutions, that the medical officer may re-vaccinate any one under ten years of age, whose primary vaccination he deems to have been inadequate, and who has not before been successfully re-vaccinated.

THE HYGIENIC SIGNIFICANCE OF RE-VACCINATION.⁸

Dr. R. Gerstäcker in a paper with the above title, gives some valuable data compiled from the reports of the Imperial Board of Health, and also from the

report of the Vaccination Committee. From their tables it appears that the mortality from small-pox in Prussia, formerly differing but little from that of other countries, has fallen to a minimum under the operations of the vaccination law, so that small-pox may now be considered as having disappeared, except in some frontier districts, while Austria, with her defective regulations as to vaccination and still more so as to re-vaccination, suffers severely from small-pox. Dr. Gerstäcker presents the following table as to the mortality from small-pox in London and in Berlin, with the comment that, while London enforces vaccination of the children, it has not enforced re-vaccination. He attributes the difference in the relative mortality from small-pox in the two cities to these facts.

DEATHS FROM SMALL-POX, PER 100,000 INHABITANTS.

	1875	1876	1877	1878	1879	1880	1881	1882	1883
In London	1.3	20.8	71.0	38.8	12.1	12.5	61.9	11.1	3.4
In Berlin	5.2	1.8	0.4	0.8	0.7	0.8	4.7	0.4	0.3

The percentages in the following table, for a period of six years, also present further evidence of the advantages of re-vaccination.

THE TOXIC PRINCIPLE OF EXPIRED AIR.⁹

Drs. Brown-Séquard and d'Arsonval have presented a communication to the Academy of Sciences, intended to demonstrate the existence of a toxic principle in air expired from the lungs of men, or other animals. The facts hitherto known are the following:

(1) Expired air almost always, if not always, contains ammonia, but in a quantity insufficient to account for the injurious action of such air.

(2) Expired air contains a small quantity of organic matters, which, if they are not already decomposed on leaving the air-passages, yet have a marked tendency to rapid change.

(3) Confined air, charged with pulmonary exhalations, is not injurious, on account of the carbonic acid contained in it. Atmospheric air to which one per cent. of carbonic acid has been added causes but little

⁷ Order of Local Government Board, Feb. 3, 1888. London, 1888.
⁸ Deutsche Vierteljahrsschrift für öffentliche Gesundheitspflege, Vol. XX, p. 87, 1888.

⁹ Journal d'Hygiène, No. 595, February 16, 1888.

inconvenience, while expired air containing no more carbonic acid is extremely noxious.

Experiments were conducted in which rabbits were treated with injections of water containing the toxic principle of pulmonary mucus.

The primary effects were: dilation of the pupils; slowing of the respiration; paralysis, especially of the lower extremities; rapid diminution of temperature from half a degree to five degrees C.

In larger doses there were more pronounced symptoms: trembling and general convulsions; attitude *recroquevillée*; choleric diarrhoea, continuing till death ensued, in three or four hours after the injection.

The conclusions of the experimenters are that:

(1) The lungs of men, of dogs, and of rabbits in health evolve an extremely energetic poison, which is continuously exhaled with the expired air.

(2) It is probable, if not certain, that it is this poisonous agent which makes confined air injurious.

The true prevention of danger is found in efficient ventilation.

ARSENIC IN WALL-PAPER, ETC.¹⁰

The law of the German Empire of July 5, 1887, as to colors injurious to health, so far as wall-papers are concerned, is as follows: Section 7. No colors containing arsenic are allowed to be used in the manufacture of paper-hangings, furniture-stuffs, carpets, materials for curtains or garments, masks, candles, and artificial leaves, flowers, and fruits intended for sale.

This regulation does not apply to the use of arsenical mordants, or fixing-agents to be used for dyeing or printing of woven goods or textile fabrics. Yet woven goods and textile fabrics made in such manner are not allowed to be used for the manufacture of the articles named in Clause I, if they contain the arsenic in a form soluble in water, or in such a quantity that in one hundred centimeters of the finished object there are more than two milligrams of arsenic. The Chancellor of the Empire is authorized to issue particular instructions as to the methods to be employed in determining the percentage of arsenic.

DISINFECTING AGENTS.¹¹

Dr. Cash has made a series of experiments on the disinfecting properties of chlorine, bromine, iodine, and sulphurous acid, using for such experiments the contagia of anthrax and of tubercle, and making control experiments on animals subjected to the same kinds of virus without the use of a disinfecting agent. He finds (as was expected) the degree of dilution of the agent, and the thoroughness of exposure to its influence, to be elements in the destruction of the morbid properties of the virus, and is able to arrive at certain provisional conclusions as to the relative potency of these agents. Employed in solutions made of a uniform strength, proportioned to their atomic weights, chlorine, bromine, and iodine do not show any remarkable differences, though iodine would appear to be the most, and chlorine the least potent. Dr. Cash gives preference to the use of these disinfectants, and of sulphurous acid in the form of solution, rather than in the form of gas, but if they have to be employed in the gaseous form, he gives reasons for preferring sulphurous acid gas to the haloids. He

points out the consideration too often lost sight of in practice, that, as quantity of the disinfectant counts for so very much in the destruction of any disease-producing material, it is necessary to take account of the assimilation, by harmless material, of the agent designed to disinfect; wherefore the quantity of the disinfectant used must be proportioned to the amount of such other material, as well as to the amount of actual morbid matter to be destroyed.

DISINFECTION OF LIBRARY BOOKS.¹²

The danger of infection from the use of books from circulating libraries has received intelligent attention in England, and means devised for their disinfection. The principle on which disinfection is based is the vaporization of carbolic acid by heat, whereby it is claimed that its action is more potent. Heat is applied to the outer casing of an apparatus, which is fully under control, so that a temperature which might injure the books can be avoided. The heat employed is from 150 to 200 F., the books being subjected to this temperature for fifteen minutes and not injured by the process. The apparatus is said to be patented.¹³

CREMATION OF GARBAGE.¹⁴

A public crematory for the disposal of garbage has just been completed at Chicago, at an expense of about \$7,000. The structure is so located that wagons may be driven upon the roof and there unloaded, thus avoiding the expense of hoisting. The dimensions of the crematory are 53 x 91 x 28 feet. The chimney is in the centre, and is twelve feet square at the base, and ninety feet high. There are two garbage furnaces, one on each side of the chimney, each being provided with three coal furnaces for generating the heat. The interior of the garbage-burning chamber is quite large, 20 x 14 x 11 feet. The garbage and coal are received through ten openings in the roof, eight of which are for garbage. At a recent trial sixty-seven double wagon loads were incinerated between 9 o'clock A. M. and noon. This crematory is intended to receive material from a radius of one-and-a-half miles. If it proves successful five others will be built. The furnaces were found to have an excellent draught, and no odor was perceptible from the chimney.

REPORT ON PROGRESS IN SURGERY.¹

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

THE TREATMENT OF JOINT INFLAMMATIONS BY IRRIGATION AND INJECTION.

Hegar ⁶² (Hamburg) states that this method in the hands of a careful aseptic surgeon, is without danger. In most cases an anæsthetic is not required. The surface of the joint is shaved and disinfected, the cavity perforated, the contents, effusion-clots, etc., evacuated under pressure, and at once refilled with the antiseptic solution. It is then re-emptied and refilled till the wash water returns clear. Violent passive motion of the joint when full is liable to force the contents

¹¹ Sixteenth Annual Report of the Local Government Board. Supplement. London, 1887.

through a ruptured capsule into the surrounding parts and thus cause fatal poisoning. After the irrigation the small puncture-wound is covered with an antiseptic dressing and immobilized eight to ten days by a splint. The dressing is continued till the wound is healed, and sooner or later, according to the severity of the case, passive motion completes the treatment.

The writer recommends the following points for puncture:

(1) Knee. Slight effusions, directly below patella; marked effusions, external border of quadriceps extensor tendon.

(2) Ankle. Between the external malleolus and the extensor longus digitorum tendon.

(3) Hip. Just anterior or posterior to the great trochanter.

(4) Wrist. Dorsal surface just exterior to extensor communis digitorum tendon.

(5) Elbow. At external or internal border of olecranon.

(6) Shoulder. A point just below the acromion. A large trocar is recommended for the large joints and a full-sized aspirating needle (Dieulafoy's) for smaller ones. For irrigation three to five per cent. carbolic or one-tenth per cent. sublimate solution, the latter to be preferred in cases of septic suppurative. This irrigation causes distinct reaction regularly accompanied by a certain amount of capsule contraction which is unimportant if an excess is controlled by passive motion at the proper time, and is of great advantage in cases of relaxed capsule. For full details the reader is referred to Hegar's original article, which is a valuable contribution to the literature on this subject, since it is too extended to do more than mention here its salient points. Hegar has obtained excellent results from this method in cases of subacute and chronic hyarthron. Of one hundred cases of hydrops genu, ninety-nine completely recovered. In nine cases of acute hæmorrhosis of the knee, and seventy-five cases of fracture of the patella, the same was true. In eight cases of primary purulent arthritis, four recovered with a perfectly normal joint; two require an apparatus on account of relaxed ligaments, but have good motion, one, where passive motion was not permitted, recovered with ankylosis, and one died from collapse during an attack of delirium tremens.

In secondary or metastatic arthritis, as would be expected, irrigation does not give such prompt results in all cases as in simple primary synovitis. A good result can be obtained only in quite recent cases. Frequently only incision and drainage can rescue limb or even life. But irrigation is so much simpler and easier, that it is to be preferred where the joint capsule is still unruptured; incision and drainage being reserved for such cases where repeated attempts by puncture and irrigation are unsuccessful. Frequently in cases of gonorrhœal arthritis, the result was most satisfactory. In obstinate cases of acute rheumatic arthritis, also, this method seems equally valuable, as the reported cases show. Quite striking, also, were the results obtained in synovitis purulenta from acute epiphysitis and osteomyelitis. In conclusion, is a report of eighty-one cases of fungus arthritis where the although unmistakable signs of tuberculous disease existed, still the process had not advanced so far as to cause general joint suppuration or rupture of the capsule. In thirty-three the treatment had no effect. In

forty-eight it gave more or less satisfactory results. Twenty-two patients were discharged free from pain, and not requiring apparatus, and fifteen with normal motion. Of the remainder, the inflammatory symptoms were relieved, but apparatus was necessary to enable the patient to continue his occupation.

REMOVAL OF MARROW AS PRIMARY TREATMENT OF ACUTE INFECTIOUS MYELITIS.

This method of treatment is again brought to notice by a report of Dr. Tscherning,⁵³ where it seems to have given satisfactory results. Assuming that the principal indication for treatment in these cases, as in all phlegmonous inflammations, is complete removal for pus, and also since the entire marrow of a bone can be removed without endangering its vitality and growth, the writer removes the suppurating marrow through two openings in the bone, large enough for the purpose, and thus drains the interior. If no distinct change exists on the surface of the bone the first opening should be made near the epiphyseal junction and so as to be most favorable in the usual position of the patient for the escape of pus. This treatment without, avoids as far as possible, the danger to life and the destruction of bone, resulting from the disease, with the least possible sacrifice of osseous structure. Of twelve cases reported, two only (myelitis of the tibia and recurrent osteomyelitis of the humerus), were in adults. In all was the function of the limb more or less preserved, and also where serous or purulent inflammation of the joint, epiphyseal separation and metastasis coexisted. Only in three-fourths cases did the affection assume the malignant type. In the others an early operation prevented any extensive disturbance. Tscherning would operate in all cases even in most malignant ones or where total separation of the periosteum has occurred, since the operative interference does not increase the danger and will generally give good results in a relatively shorter time.

IODOFORM IN SURGERY.

The question of the true action of this drug still continues to be the subject of investigation. Schnirer,⁵⁴ at Vienna, has contributed the results of his experimental work, done at the laboratory of v. Frisch, which supports the assertion that iodoform has no antiseptic action. In combination with an efficient germicide, its action not only as a protective covering, but also from its analgesic property and power to diminish wound secretion, is a valuable one in the treatment of wounds. Iodoform gauze is the form especially recommended.

Senger,⁵⁵ in August, 1887, published an exhaustive article describing his investigation of the action of iodoform with anthrax bacilli. He decided that the growth of these germs was checked by the drug; that the action was a chemical, not a mechanical one. He claims that in the animal organism iodoform showed a vigorous anti-bacterial action, which was, however, not an immediate one, but which was developed gradually, and after a certain time; also, that this action in living tissue was not a general one, but merely local. This opinion seems to coincide with that of the majority of recent investigators. Also where serous oozing threatens the integrity of a

Clinical Memoranda.

CANCER OF THE TONGUE. COMPLETE EX-TIRPATION BY A BLOODLESS OPERATION.¹

BY H. H. A. REACH, M.D.,
 Surgeon to the Massachusetts General Hospital.

THE patient was a woman fifty-six years old, who had always enjoyed good health. Fifteen years ago she touched her tongue with lye and burned a small spot on the dorsum. Soon after, she noticed a thick white coating, which remained until one year and a half ago, when it disappeared, leaving a smooth red patch upon which could be seen a few pimples. Several months ago this spot showed signs of ulceration, and soon presented a deep cavity about an inch in diameter, in the middle of the organ, partially filled with exuberant granulations, at one point showing some attempt at cicatrization. There had been no pain nor hæmorrhage. At the time she entered the hospital, the base of the ulceration was indurated, irregular and appeared to involve about one-half of the tongue. At one point the growth presented a small slough. I was unable to obtain any evidence of specific disease, but to eliminate that question from the diagnosis, she was placed upon a mixed treatment for three weeks, with a negative result so far as any change in the growth was concerned. In the meantime she had begun to suffer from almost constant pain in the tongue, which radiated from it as a centre to the sides of the jaws and on each side of the face to the temporal region.

OPERATION.

The patient was thoroughly etherized, the lower jaw pried down and a wooden gag inserted, so as to give ready access to the tongue, which was drawn out of the mouth by double hooks. A chain écraseur was then carefully adjusted around the tongue in front of the epiglottis and slowly tightened; the tongue meantime held taut by the vulsulum forceps. As soon as the chain had begun to make a track for itself the screw was made to revolve once every two minutes by the watch. In exactly forty-six turns the section was complete. No hæmorrhage and very little pain followed the operation. She swallowed milk easily after recovering from the ether. She was discharged from the hospital at the end of two weeks, well and able to make herself easily understood.

Four months afterwards she was in excellent condition and had improved so much in her speech that she was able to act as one of a committee of ladies at a

¹Read before the Boston Society for Medical Improvement, March 12, 1888.

fair, and to quote her words, "could make herself understood almost as well as ever."

Dr. W. W. Gannett has kindly made an examination of the specimen presented, of which the following is his report: The specimen is the tongue amputated at the base; total length 7 cm. In the middle of the upper surface is an ovoid ulcer measuring antero-posteriorly 3.5 cm., transversely 2.5 cm. The long diameter is in the long diameter of the tongue.

The ulcer at the edges is shallow, gradually deepening so that in the middle it has a depth of .7 cm. As the specimen was received in alcohol, no description of the appearance of the ulcer in the fresh state can be given.

The microscopic examination showed the base to be made up of many layers of flat epithelium with long, solid, finger-shaped masses of epithelium projecting far into the substance of the tongue. In many of these masses were well-marked onion-bodies. The deeper layers of the tongue around the new growth showed extensive round-cell infiltration. I think that all the new growth was removed.

Diagnosis: Flat-cell cancer of tongue.

HYSPADIAS.¹

BY H. H. A. BEACH, M.D.

A CASE ILLUSTRATING THE IMPORTANCE OF EARLY DIAGNOSIS.

THE case occurred in the practice of Dr. Hastings, of Warren, who detected the true condition of the parts, and to whom I am indebted for the opportunity of making an examination. The subject was sixteen years old, and appeared in girl's clothing, such as he had always worn. With the exception of a changing voice, a little hair on the upper lip, a slightly awkward and boyish gait, there was nothing to suggest the male gender. He was well developed generally, and in good health. There has been no sexual desire in either direction, and he did not seem to know that he was different from other girls, having been a regular attendant at a High School in company with others of that sex. He was bright, preferred the society of boys, and was the leader in all games, including baseball.

The breasts were undeveloped. Upon an examina-

¹ Read before the Boston Society for Medical Improvement, March 12, 1888.

tion of the genitals, two well-developed testicles were found with the spermatic cord, easily demonstrated to the external abdominal ring on each side. The penis was short and imperfectly developed, and presented a well-marked hypospadias; the everted mucous membrane of the urethra was smooth, shining, and very sensitive. It was in such contrast to the adjoining scrotum, which projected on each side of the cleft in a way to easily suggest the appearance of a vulva in a young child, with the vagina between. The glans penis was fairly developed, with a depression where the meatus should be found. The urine was passed through two fistulous openings in the perineum; a third and adjoining opening permitted the discharge of fecal matter. There was no evidence of any external sphincter muscle. When the discharges were thin they were only partially controlled. There was fairly good control of the bladder. The pubic hair was well developed.

CASE OF VESICAL AND URETHRAL CALCULUS.¹

BY A. T. CABOT, A.M., M.D.

FRANK K., fourteen years old, entered the Massachusetts General Hospital, August 4, 1887. He had suffered from urinary symptoms for eight years. Some years ago he had a kick in the perineum, which was followed by great aggravation of his trouble, with much pain in the bladder and penis. Urination had, from the first, been very frequent, and there had been at times hematuria.

Recently the pain had been much more severe than before, and the water was voided with much straining as often as several times an hour.

The urine was pale, had a specific gravity of 1012, was acid, and contained a trace of albumen. The sediment, which was abundant, consisted of pus and mucus. The sound touched a stone seemingly in the urethra, just below the pubic arch. Examination by the rectum showed the stone to be a large one.

August 11, 1887. The boy was etherized, and a grooved staff was passed along the urethra below the stone into the bladder. Upon this as a guide, the usual incision for lateral lithotomy was made.

It was then found that the stone reached from the bladder forward through the prostatic and membranous, and well into the bulbous urethra.

An effort was made to push it back towards the bladder, so that its anterior end, which projected in front of the incision, could be brought out first. This did not succeed, owing to the firm grasping of the stone by the surrounding parts. Accordingly, the end which lay in the bladder was seized and drawn out through the wound, so that the whole stone was thus turned end for end, and dragged out of the urethra with some difficulty.

Another smaller calculus was then discovered in the bladder and removed. There was no hemorrhage requiring ligation. The operation was followed by

¹ Read before the Boston Society for Medical Improvement, March 12, 1888.

no fever, and the pain, which had been so distressing before, was entirely relieved.

At the end of eight days the urine all passed by the urethra, and in sixteen days the boy was discharged well.

The small end of the stone to the right projected into the bulbous urethra; then comes the constriction, which was grasped by the compressor urethræ muscle. The largest part of the stone, in which the cross-section shows the nucleus, lay in the prostatic urethra, which was much distended by it. Behind this is another constriction, where the involuntary sphincter at the neck of the bladder moulded the calculus, and the portion to the left of this in the cut lay in the bladder.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

F. B. HARRINGTON, M.D., SECRETARY.

MARCH 12, 1888. The President, DR. O. F. WADSWORTH, in the Chair.

DR. R. M. HODGES read a paper entitled
CONSTIPATION AND SOME OF ITS ACCOMPANIMENTS.

The following is an abstract.

Constipation is largely due to influences growing out of a high degree of civilization; among which residueless food and imperfect nutrition are predominant.

Constipation means not only infrequent and difficult defecation, but also incomplete defecation. The mischief occasioned by constipation, is chiefly owing to the mechanical effects of the "straining" which accompanies attempts at defecation. To get rid of straining is to deprive constipation of most of its detrimental consequences.

Fæcal retention from incomplete evacuation of the bowels may give rise to a form of blood-poisoning consequent upon an auto-infection of the system by the products of fæcal decomposition within the intestine, the symptoms of which are either acute or chronic, and not infrequently alarming. Such an occurrence is to be guarded against by watchfulness directed to indications of anemia, dyspepsia, and loss of appetite, especially in early childhood and in female adolescence, and by the careful observation of the temperature in cases of convalescence from sickness, or of those confined to their beds from any cause whatsoever. Phenomena of great suddenness and apparent severity may owe their origin to the rapid formation and quick absorption of intestinal poison. Four cases illustrative of this point were narrated.

The relief of constipation requires the bowels to be supplied with a sufficiency and proper consistency of feces to work the machinery of defecation. This can only follow the ingestion of a commensurate bulk of food; and by the intestinal contents being kept soluble by a proper consumption of liquid. Experience proves that hot water, pure spring water, aerated water, have nearly, if not quite as much, laxative efficiency as those which are called "medicinal."

The constipated often undertake to "regulate their diet," as they say, by avoiding those articles of food which are supposed to be "binding." What these are in any ordinary domestic dietary, it would be difficult

to enumerate with any well-founded accuracy. Articles taken as food because they are thought to promote movement of the bowels, do this to a trifling extent, if at all, and only when, eaten in considerable quantity, they leave a large amount of residue. Coarse and hearty food of any kind, leading to bulky feces, prevents constipation. Fruits owe whatever cathartic value they possess chiefly to the water they contain, or to a lavish consumption which leaves a superfluous and unassimilable residue behind. Dried fruits are distinctly constipating.

Sluggish action of the intestines should be unhesitatingly discouraged by drugs and by enemata, both of which must be administered in small doses, of the former so small as to be given twice if not three times daily. The regular use of laxatives is no worse a habit to contract than that of taking tea or coffee, or of using tobacco. Given directly after the bowels have been moved, enemata have the same diagnostic value in determining whether or not the rectum has been emptied, that the catheter, used immediately after micturition, has in deciding whether the bladder empties itself or not.

Sedentary habits do not, of themselves cause, nor does walking — leg-exercise — usually relieve constipation. Exercises in which another set of muscles than those of the lower extremities — the latter being, as a rule, already tired by the standing and walking of daily occupation — is brought into action, are far more likely to promote regularity in the movement of the bowels than the "constitutional" which are sometimes encouraged by medical advisers.

With invalids and enfeebled persons a longer period of rest between the acts of defecation is oftentimes demanded than is the case when a daily movement takes place.

DR. FRANCIS MINOT said: It is hardly necessary to say that we are all very much indebted to Dr. Hodges for his extremely wise and sensible remarks upon this subject: a subject with which we are all of us, perhaps, too familiar. In some respects, I should be inclined to differ a little from him in his views, but in general, I must say that he has given us a most excellent method of treatment of constipation of the bowels.

I think that constipation is by no means such a common trouble now as it used to be, owing to progress in knowledge of physiology, in modes of living, in diet, and in cooking; still we do see extreme instances of it. I have at this moment under my care a lady who had been subject to constipation for several months before she came under my care. Under laxative treatment for two months, beginning January 1st, she had three or four large solid dejections daily, and it was not until about the first of this month that the bowels could be considered to be fairly relieved of this large accumulation. This state of things was accompanied by symptoms that were at one time alarming, intense pain in the abdomen, distension, and others, looking a little like peritonitis, but which passed away after the true condition of things was discovered.

I recollect well the late Dr. John Ware saying that a small pill of aloes or some other active cathartic, given once or twice or three times a day, could not do half as much harm as an enormous quantity of oatmeal or rye-meal or indian-meal pudding, which some people took every day of their lives in order to keep their bowels in decent condition. A well-known

physician of this city who died after a long illness, and who felt bound, I suppose, in conscience, to take the treatment that he had ordered for his patients, eat a plateful of oat-meal porridge every morning, saying that it was the most detestable thing he had to do.

A grain of aloes, three times a day, before meals, is one of the most admirable of all laxatives. I think, though, that prevention is better than cure, and that prevention is more easily obtained by a variety of food than in any other way. Many of us live in a stereotyped fashion; we eat similar things for breakfast, dinner and tea, with but little change. We have one thing Monday, and one thing Tuesday, etc. When a man dines out, he generally finds his bowels in a better condition the next day; partly because he eats more and partly because he has changed his diet. He gets things that he is not accustomed to get at home.

Regular systematic exercise in the open air, I don't mean fatiguing exercise, often has the happiest effect, which is increased by daily bathing. And yet we find people, especially women, who never touch cold water if they can help it.

In regard to medicines, I have spoken of aloes. I presume everyone has his favorite pill which he prescribes. I will simply allude to one old-fashioned remedy which I think is not worthy the neglect into which it has fallen in consequence of the great number of medicines which we have now, and that is the extract of butternut. This extract in a dose of from fifteen to thirty grains, is an admirable laxative and has the advantage of being cheap. It can be taken in the form of pills, or can be simply eaten. I saw a gentleman once who showed me a bucket which held, I suppose, six quarts or more, full of the extract of butternut, which he ordered from the Shakers, and he said it lasted him a year. In consequence of some paralytic trouble, he was bed-ridden, and suffered a good deal from constipation, but with this remedy he was able to get on very well.

I agree with Dr. Hodges that enemata should be small in bulk. They should rarely exceed one-half a pint, and less than that is enough. Plain water is often sufficient. Sometimes the addition of a little soap-suds "greases the ways," as Dr. Hodges has said. Perhaps, too, a little salt is a good addition.

DR. ABBOT said that he could add little to what had been already so well said on the important subject under consideration, but he thought gentlemen might be interested at this time in some experiments he had been making within a few days in the use of enemata of glycerine, which had been recently strongly recommended as a remedy for constipation in the *British Medical Journal*.

To thirteen Hospital patients under his charge—seven being cases of acute disease, six of chronic—twenty-four injections of glycerine had been given with successful results in all but three of the patients. In some of them the action of the bowels followed immediately, in most of them within fifteen or twenty minutes, in a few somewhat later, but in all within an hour. In twenty of the enemata the amount injected was one drachm, in the rest two drachms. Similar good results followed in two private patients, who had for a long time depended entirely upon cathartics or injections to move the bowels. In both of them the injection of two teaspoonfuls of glycerine caused an immediate and thorough evacuation, such as had rarely followed the

means they had usually employed. In all the cases the glycerine was administered without any addition as a vehicle. In only one instance was there the slightest discomfort in the use of this remedy, and in this it was transient.

As an explanation of its mode of action, Dr. Abbot was inclined to refer it to the local stimulating power of the glycerine, which started up a general peristaltic action very much as the common domestic remedy for constipation in young children—the introduction of a piece of soap into the rectum—produces an evacuation.

DR. C. F. FOLSOM: It is interesting to see how much slight measures will do in some cases, especially in the case of young ladies who live in the country or the suburbs, where the walking is bad. They don't get regular exercise, and quite a number of cases that one sees have a sluggish circulation, and they generally tell you that they cannot take baths, because they feel chilly five or ten or fifteen minutes afterwards. I find a very large number of cases with this and other symptoms, of which neuralgia is a common one. By taking a sponge-bath, and then pulling the chest-weights, a light pair, such as can be obtained for ladies, for five or ten minutes, especially with the back toward them, so as to exercise the abdominal muscles, we can get surprising results.

I have also had a number of cases, the nature of which I stumbled upon by accident. One young lady had been troubled with intolerable constipation for a good many years. It was found that when anything happened that produced mental effort she had a movement easily; and in that class of cases, if you give them almost anything, the simplest thing possible, and tell them it is going to produce a movement at a certain time of day, the mind is fully fixed upon that fact, and you very often get it.

DR. H. H. A. BEACH: I have been very much interested in Dr. Hodges's paper, and can testify to the measures that he speaks of, and also that of Dr. Abbot. Speaking of oatmeal, there is a danger which I don't think is generally recognized, and that is the possibility of the impaction of a lot of oatmeal hulls, the hulls projecting from the surface of the faeces and producing irritation. In a case that I recall there was a peritonitis, which went on to death, and at the autopsy, which I made (it was in a case of Alfred Hosmer, of Waltham; the patient had been sick about ten days, I think, and died of peritonitis) was found a small body, about the size of a peanut, consisting of impacted faeces, with these oatmeal hulls projecting from the surface like the sharp points of a cockle-bur, and that had been impacted in the appendix, causing abscess and death. It was very easy to make that out. Of course, if that could occur in the small mass, it might in a larger one. Strained oatmeal does away with the danger, of course.

DR. JAMES AYER: Of course, oatmeal is laxative. In regard to Dr. Hodges's treatment by small, laxative pills after each meal, I suppose that it may be considered to be proved the best way in most cases of constipation.

I could mention the case of a gentleman to whom small doses of aloin were given after meals for several months; then a pill of aloin, nuxvomica, and podophyllin. After a time they were given every other night, sometimes half a pill being sufficient. Finally the patient was almost well, but there was still some

constipated habit left — perhaps five operations a week, instead of seven — and he tried gluten suppositories, and is now using them with great benefit. I always supposed that it was from lubricating the lower part of the intestines.

Dr. HOMANS, 2d: Dr. Minot says that every one has his favorite cathartic pill, but I think there is one other treatment — the fluid extract — that is extremely good, and especially the fluid extract of cascara sagrada, which seems really to do what it is claimed to do; that is, it not only moves the bowels, but by a constantly decreasing dose. A very good article was read on that at the last meeting of the Massachusetts Medical Society. I have used it in two or three cases, and in every one I started with twenty drops at night. All three were cases of confirmed constipation, and at the end of two months the dose was reduced to five drops, and finally stopped entirely, with the result of curing the patient.

It seems to me that in a discussion of this sort it should be mentioned, because it does seem to work in the majority of cases. Dr. Farlow reported one hundred cases, I think, in which something like sixty per cent. were benefited.

Dr. P. C. KNAPP: Shortly after reading Dr. Farlow's paper I was treating a gentleman from Pennsylvania who had been a victim of constipation, with other troubles, for a considerable time, and his physician had been treating him with calomel, with the result that his bowels got in a bad condition. I started first with ten minims of the cascara, and afterward was obliged to increase it to fifteen, but in three or four weeks he succeeded in reducing the dose to three minims, which he continued twice or three times a day with the utmost satisfaction to himself. I tried it also during the summer with good results, finding, after a week or so, that I had to diminish the dose, and during the fall and winter I have used that to the exclusion of almost every other drug in the treatment of habitual constipation; and in most cases I have found that, starting with ten drops three times a day, in a couple of weeks the dose could easily be diminished or abandoned.

Dr. JOHN HOMANS: If I am not very much mistaken, Dr. Minot's favorite laxative is very largely used now under the name of "castoria." Castoria is the extract of butternut, I think. I affirm it with some hesitation, but that is my belief.

Dr. MINOT: I should like to ask if any gentleman can tell me if there is any essential difference between the fluid extract of cascara and the old-fashioned syrup of buckthorn.

Dr. JOHN HOMANS: I think it is a different drug. The cascara grows upon the Pacific slope; this grows somewhere else.

Dr. A. T. CABOT showed

A LARGE URETHRAL CALCULUS REMOVED BY OPERATION.¹

Dr. H. H. A. BEACH presented

A CANCEROUS TONGUE COMPLETELY REMOVED BY A BLOODLESS OPERATION.²

Dr. BEACH reported

A CASE OF HYPOSPADIAS ILLUSTRATING THE IMPORTANCE OF EARLY DIAGNOSIS.³

Dr. JOHN HOMANS presented

A CANCEROUS TONGUE,

and said: When I saw the notice of Dr. Beach's specimen, it occurred to me that I would bring up a case that I operated upon Saturday. It was a much more extensive disease than in his case. The patient is a medical man who graduated at college the year after I did, and his first symptom had appeared the middle of last December. Soon after that, noticing an ulcer upon the left side of the tongue, he consulted Dr. Langmaid, who put him on specific treatment, with no amelioration of his trouble, and in the latter part of February he came to the Hospital. The disease occupied the left side and middle of the tongue. It has been removed in two pieces, and you can see a section of it here. The disease had invaded the floor of the mouth, and had run up the pillar of the soft palate.

Being a medical man, he understood the gravity of the thing and the severity of any operation that was to be done, and there was a consultation of surgeons. Five were present: three advised doing nothing, and two thought that it had better be left to the patient to decide. He decided to have something done, and I removed the tongue last Friday, making an incision parallel with the jaw, and over the ramus and symphysis of the jaw, and then opening the mucous membrane, after stopping the bleeding, and pulled the tongue through the artificial opening thus made; but, the disease having involved the muscle, it would not come out, and I applied the écaraseur as far back as I could. The first time I took off three-fourths of the tongue, and having freed the floor of the mouth and the anterior muscles down to the hyoid bone with scissors, I then applied the écaraseur again just in front of the epiglottis, so that the entire tongue has been removed, and the muscles of the floor of the mouth. Then, with the scissors, I removed the pillar, and the disease, which had run up to the styloid process along the stylo-hyoid muscle and stylo-glossus, and the only portion that I didn't get out was in the pterygoid fossa, where I could not reach with the nail quite all the disease.

The operation was a pretty severe one, and I felt rather anxious about the Doctor, but found him, the next morning, up and reading the newspaper. I could understand perfectly what he said, although we have not encouraged his talking. He thinks he could swallow if we were to take the drainage-tubes out. He says that anything he takes runs out of the tubes. He is fed through a tube without much difficulty. The object of removing a disease so extensive as this is simply the relief of pain, which it does do for a time. I don't suppose there is any possibility of doing anything more than that.

Dr. Homans also showed a fatty tumor and an ovarian cyst.

Dr. BEACH also reported a case of

MULTIPLE FATTY TUMORS.

Patient a man, thirty years old. The first one appeared seven years ago, near the elbow; since then they have invaded the hips, thighs, and shoulders. Twenty-eight were removed, varying in size from that of a cherry to a hen's egg. Twenty-six of the wounds united by first intention. He was discharged from the Hospital, well, in two weeks.

¹ See page 375 of the Journal.

² See page 374 of the Journal.

³ See page 375 of the Journal.

TUBERCULAR JOINT-DISEASE.

DR. C. B. PORTER showed by card a foot which had been amputated for caries of the tarsus. The patient was a girl, twenty-two years of age. One year ago, there was a slight injury of the ankle. For six months she had been treated by a stiff bandage. An opening formed below the external malleolus, communicating with the joint. The disease steadily progressed, until amputation became necessary.

DR. J. C. WARREN showed by card a knee-joint which had been amputated for extensive tubercular disease, involving the entire joint. The patient was a boy, fifteen years of age. Family and personal history good. Three years ago, without injury, pain and swelling of the right knee-joint appeared. The disease became so extensive that excision was impossible, and the leg was amputated. The patient was greatly improved. Dr. Warren also showed a tubercular wrist which he had amputated. Seven months ago the man, aged fifty-three years, had sprained the wrist. The carpus was very extensively diseased.

UNUNITED FRACTURE OF TIBIA AND FIBULA; RESECTION AND WIRING.

DR. E. H. BRADFORD showed by card the portions of resected bone from a patient with the following history: Two and a half years ago, a boy now four and a half years of age injured its leg while alone for a moment on a hassock. The child was found crying from pain in the leg. The family physician called six hours later, but could discover no break. He was then absent from town for seven weeks. For two weeks the leg was swollen and painful, then the child crept about, but could not bear its weight upon the leg. Was treated with liniments. When the physician returned the child was examined under ether, and a fracture was found. It was put up in a felt splint. This was worn for four or five months. The leg being still ununited, a shoe, with an upright to support the leg, was worn until the present time.

March 8th, Dr. Bradford operated. A ligamentous false joint was excised with bone-forceps, and the ends sawed square. The divided tibia was wired with silver wire. The wound was closed with catgut sutures. It was dressed with iodoform powder and "corrosive gauze," over which was placed a plaster bandage from toes to knees, while the foot was held in correct position. Two wires were inserted in tibia, none in the fibula. The patient was doing well.

LARGE CYSTIC TUMOR OF THE BREAST.

DR. BRADFORD also showed a large cystic tumor of the breast which he had removed from a woman of eighty-two years. The cyst contained over a pint of bloody fluid. Microscopic examination of the solid portion showed the characteristic stroma and cells of carcinoma. The patient was doing well three days after operation.

TUBAL PREGNANCY; RUPTURED WALL; MIGRATION OF THE OVUM.

DR. JAMES A. DOW, of Cambridge, said: The history of the case that I can give will be very meagre indeed. On Thursday, last week, I was summoned to this patient, a woman whose age was thirty-three, who had borne five children, the last two years of age. Since that time she had menstruated regularly up to within two or three months. This history I obtained from the husband, and not from the patient, whose

condition was such that I could not get much history when I first saw her. Within the past six weeks she had menstruated, her husband said, three times. At any rate, she had had three periods of flowing, though, of course, it was a question so far as menstruation was concerned. In addition to this, during all her married life she had been so constipated as to go five or ten days without movement of the bowels, and just previous to this attack she had had one of her bad spells of constipation. On this day, Thursday, about eleven o'clock, while at stool, straining, she said something gave way, and caused her intense pain. She fainted, and one of her children ran into the next door and called a lady, who came in and found her upon the floor.

It was twelve o'clock when I arrived. I found her in a rocking-chair, almost pulseless; there was a faint pulse at the wrist. I put her upon the bed and gave her some stimulants, which improved the pulse a little. But nausea and vomiting had taken place previous to my arrival. She sank rapidly, being unable to swallow anything, and died an hour and a half after my arrival. The autopsy was made by Dr. A. F. Holt the following morning, and the specimen is in Dr. Fitz's possession.

DR. R. H. FITZ showed the specimen, and described it as follows: The uterus, soft and pale, with slightly thickened walls, measured internally three inches in length, and two inches at the greatest width. The lining membrane of the body was thickened, wrinkled, soft, and pliable, and of an opaque, gray color. At the upper right-hand corner of the uterus was an ovoid body, of the size of a small almond. It was contained between the peritoneal layers of the broad ligament. It projected posteriorly, and was in intimate contact with the uterus, but on the peripheral side of the round ligament. It had been opened longitudinally, and was hollow and empty. The wall was a third of an inch or less in thickness, and was lined with a shreddy material, in which dark-red blood-clots were entangled.

The microscopic examination of the shreds showed the structure of chorionic villi. There was no false membrane on the serous surface of the sac, nor fetal membranes within, excepting the villi already mentioned.

The uterine end of the right tube traversed the wall of the uterus, and was obliterated in the immediate vicinity of the sac. A probe passed through the fimbriated opening and along the tubular canal entered the cavity of the sac. The lining membrane of the tube throughout was tense, smooth, shining, and translucent, without thickening.

In the left ovary was a corpus luteum, three-fourths of an inch long and a half-inch wide.

Recent Literature.

The American Journal of Psychology.

The first two numbers of this new journal, which is edited by Prof. G. Stanley Hall, of Johns Hopkins University, have already appeared. Its object, as stated in its first number, is "to record the psychological work of a scientific, as distinct from a speculative character, which has been so widely scattered as to be largely inaccessible save to a very few, and of-

ten to be over'looked by them." It is therefore addressed to "teachers of psychology in higher institutions of learning; biologists and physiologists; anthropologists who are interested in primitive manifestations of psychological laws; physicians who give special attention to mental and nervous diseases; all others interested in the great progress recently made in so many directions in applying more exact methods to the study of the problems of human feelings, will and thought." Such a journal should be welcome to the members of these varied classes, for it is the first periodical in English which presents the new physiological psychology.

The original articles in the two numbers of the *Journal* which have thus far appeared, are, on the whole, valuable and interesting contributions to our knowledge. Lombard's paper on the knee-jerk has already received notice in these columns.¹ Hall and Motora, from careful study of sensitiveness to gradual pressure changes, have found that Weber's theory of a definite ratio of sensitiveness cannot be accepted without reserve, that sensitiveness is subject to marked individual variation. The other chief contribution to pure experimental psychology is Jastrow's careful consideration of the psycho-physic law. In the last number the physician's attention, however, will be sooner attracted to Donaldson's review of the relations of neurology to psychology, and Cowles's minute and thorough study of a patient with insistent and fixed ideas.

Of even greater value than the original contributions are the admirable reviews and wide-reaching retrospects of the various contributions to our knowledge of the mind and nervous system, which take up a considerable portion of each number, and, by themselves, are enough to commend the journal to the physician. Among them we must note the admirable and critical review of that mass of literature relating to psychical research, which has already reached so portentous a bulk. It may be added that, although the bulk of this review is much less than that of the subject reviewed, its weight is far greater.

Physiological psychology is only just beginning to clear itself from the fogs of metaphysical speculation, and, as yet, too little attention has been paid to it in this country. We trust that this new journal will be able to keep good its promise to avoid speculation and controversy, and we commend it to those of the medical profession — who should be many — who are interested in the scientific study of psychical processes.

Treatise on Human Physiology, for the Use of Students and Practitioners of Medicine. By HENRY C. CHAPMAN, M.D., Professor of the Institutes of Medicine and Medical Jurisprudence in the Jefferson Medical College of Philadelphia, *et cetera*. Philadelphia: Lea Brothers & Co. pp. 915, and 605 illustrations.

In this handsome volume, Professor Chapman has endeavored to satisfy "a want felt by students and practitioners of medicine for a systematic work representing the existing state of physiology and its methods of investigation, and based upon comparative and pathological anatomy, clinical medicine, physics, and chemistry, as well as upon experimental research" — at least, such is the purpose set forth in the preface. To this end the author has pleasantly de-

tailed the results of his extensive reading in sixty-five chapters, adding with great liberality clear explanatory illustrations of structure or of pieces of apparatus from the works of standard writers, as well as numerous drawings of his own dissections, and of special pieces of apparatus belonging to the extensive experimental equipment of his own laboratory. Probably no American work on physiology was ever more admirably illustrated, and perhaps none has given a more entertaining account of certain phenomena; for example, the electrical physiology of nerves and muscles, and the physical aspects of sight and hearing.

The most interesting feature of the book is one which finds no mention in the preface. We allude to the frequent statements about the historical development of the particular question under discussion. It is a good thing that the student should be reminded again and again that the physiology of to-day is not based merely upon the researches of last year or yesterday, but that other and often greater men have labored long and earnestly and cleverly, and that we of to-day are the heirs of their methods and of their knowledge. Fresh researches crowd upon us so rapidly in this "age of Centralblätter," as it may be called, that Professor Chapman has done a real service in reminding the student of the glorious past, from which he cannot separate himself if he would.

And yet it is just this interest in the older history of his specialty that has prevented the author from making his book what we wish it were — a book fully up to the times. The views of older writers and experimenters on many points are given with fairness and sufficient detail, but far too frequently, we look in vain for the great transformations which more recent and often more exact researches have brought, and which the student ought to find in such a volume. It is on this point that the book fails to satisfy us, and this is all the more regrettable because we find plenty of incidental information that Professor Chapman is not ignorant of these researches. This defect is met with in many places, but is especially prominent in the earlier chapters of the book — those on the "proximate principles" and on digestion.

We have delayed this notice longer than was originally intended, because we found so much that was valuable to offset many objections that came up as we read. The printer and proof-reader have made sad work of some names and words, but it would be unprofitable to note them now, or to make the few necessary corrections of the copious index.

— The Anthropometrical method of identifying criminals, originating from Paris, has, says *Science*, been adopted in the prison at Joliet, Ill. In addition to the photograph of the prisoner, accurate measurements of his height, the length and width of his head, the length of the left middle and little finger, of the foot, the fore-arm, the ear, the stretch of the arms, description of scars, the color of the eyes, and so on, are recorded; and it is thus possible to identify prisoners assuming false names with far greater ease than formerly. In the two years that the system has been in operation in Paris, 826 habitual criminals arrested under assumed names are said to have been identified. Besides the practical utility of the system, it amasses very valuable statistical data contributing to the natural history of the criminal classes.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, APRIL 12, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

CEREBRAL LOCALIZATION.

DR. BROWN-SÉQUARD has just published a paper in the April number of the *Forum* on Cerebral Localization which, although written for the non-scientific public, is certainly worthy of consideration. It cannot be said that Brown-Séquard's views are new; they date back to the time of Flourens, and Brown-Séquard himself has been maintaining them for nearly twenty years, but not even Goltz has taken so pronounced a stand against the doctrines now so generally accepted. The question in regard to the functions of the brain is, as he puts it, "whether localization exists in aggregated masses of nervous elements, all endowed with similar functional powers, forming a special organ, a distinct, well-defined cluster of cells and fibres; or whether it exists in nervous elements disseminated in many parts of the encephalon." This last opinion, which he says is gaining ground, is the one which he maintains; the evidence in favor of the existence of cluster-localizations, either by exciting or stimulating such centres, he is strongly disposed to reject. Experiment has shown not only that identical effects can arise from the stimulation of widely different parts of the brain, but that each part of the brain can be destroyed without any cessation of function. A function may disappear, without any organic alteration of the elements in which it was located, due to irritation coming from some distant part, even the irritation of intestinal worms, which may cause paralysis, insanity, blindness, etc. "Every destruction or removal of a part, however small, of brain tissue takes away contributors to several or to many functions"; but the nervous elements remaining are evidently sufficient for the performance of these functions.

Brown-Séquard next considers the various functions which are supposed to have their seat in the brain, such as intelligence, consciousness, speech, memory, sensation, and motion. He begins by admitting the possibility of centres for perception and voluntary

motion in the spinal cord, and then advances the hypothesis that one-half of the cerebrum is enough for all intellectual functions; that the idea that one hemisphere presides over the sensibility and the voluntary movements of the opposite half of the body is erroneous. The intellect is situated in elements scattered through the gray matter of various parts of the cerebrum, but he seems less certain about the localization of consciousness; at least, he claims that considerable portions of both hemispheres may be destroyed without the least diminution of consciousness, but loss of consciousness may arise from inhibition from irritation in almost any region. In regard to the speech-centres his scepticism is even more pronounced. Finding that many aphasic patients have still the power of uttering one or two words or phrases, and that there is still considerable discussion about the exact localization of the different centres, owing largely to the want of differentiation between the different forms of speech disturbance, affirms that "aphasia is due to the propagation of an irritation arising from the diseased place or round it, going to the cells endowed with the mental power of speech, and stop their activity by inhibition. These cells must be scattered in most parts of the two hemispheres, as we find that considerable destruction can exist in either of them or in both without aphasia." In regard to sight, he notes the older theories as to the visual centres, and the dispute between Ferrier and Munk, and asserts that one-half of the brain is sufficient for perfect perception of visual impressions coming from the two eyes. There is no cluster-localization for sensation; lesion in any part of the encephalon can cause anaesthesia, each part may be destroyed without anaesthesia, and each hemisphere is sufficient for the two sides of the body. In regard to the motor centres, he takes equally sceptical ground. After division of the pyramidal tract he has obtained extensive movements from galvanizing the cortical centres on that side. A lesion can exist anywhere without paralysis, a lesion anywhere can produce paralysis, a very limited paralysis may follow complete destruction of all the motor centres, or complete paralysis may follow very limited destruction of these centres. Motion depends upon two sets of cells, one set used in the mental part of the operation, is disseminated through the brain, the other, used to put the muscles into movement, is in the basal ganglia and the cord; each half of the brain being sufficient for performing motion in both halves of the body. In conclusion he says, "What I consider true and established is, first, that the various mental and physical functions of the brain are localized in nerve-cells so arranged that those employed for the same function, instead of being agglomerated together, are scattered about in many parts; secondly, that each half of the brain contains centres for all the cerebral functions, physical or mental."

We have given Brown-Séquard's views somewhat at length, for, although they are not new, they take more positive ground against the generally accepted

theories than is held by any other physiologist of any note. They are substantially the views which Flour-ens maintained twenty years ago, before Fritsch and Hitzig published their epoch-making monograph. They were upheld by Vulpian and some of his pupils in the face of the discoveries of Fritsch and Hitzig, Exner, Munk, Ferrier, Charcot, Horsley, Tamburini, Luciani and Seppilli, and a host of others. With the exception of Brown-Séquard and his pupils no one is prepared to maintain them to such an extent to-day. Goltz can be ranked among the opponents of "cluster localization," but Goltz is far less pronounced in his views than Brown-Séquard.

In a subsequent article we will speak of the objections to his theories.

HYSTERIA IN THE MALE SUBJECT.

WRITERS on the practice of medicine have for the greater part of this century recognized the fact that hysteria sometimes occurs in the male sex, though carefully recorded observations become fewer and fewer as one goes back toward the beginning of the century.

Within the past thirteen years, numerous monographs on hysteria in the male have appeared in this country and in Europe. Among these we may specify the often-cited contribution of Dr. J. J. Putnam in the *American Journal of Neurology* (1884); the paper of Walton in the *Archives of Medicine* for 1883; that of Dr. W. P. McIntosh in the *Medical News*, Vol. XLVIII; another by Dr. Anson P. Smith in the *Medical Record*, Vol. XXII; the valuable and much-quoted treatise of Page "On Injuries of the Spinal Cord without Apparent Mechanical Lesion, etc." (London, 1885); five theses on the subject of male hysteria defended before the Paris Faculty, 1875-1880, of which one, by Klein, contains reports of eighty cases; later still, Batault's thesis, which gives a summary of over two hundred cases, and the treatises of Bourneville, Raymond, and Dréfus, of Oppenheim and Thomas. "This question of hysteria in the male," says Charcot, "is in some sort the order of the day" (*à l'ordre du jour*).

In Charcot's last volume on "Diseases of the Nervous System,"¹ he devotes seven chapters to the study of this subject. In the first two (*Leçons*, XVIII and XIX) he shows that hysteria in the male sex is not as rare as was formerly thought. Briquet's five per cent. (that is, of one thousand cases, he reckoned fifty as cases of hysteria in the male subject) is probably an under-statement, rather than an over-statement. He sets forth the rôle of traumatism in the development of this affection. Many of those peculiar nervous states grouped under the head of "Railway Spine," and which Page thinks might more appropriately be called "Railway Brain," whether occurring in man or in woman, he regards as simply hysteria, nothing more.

The tenacity of the hysterical stigmata in grave cases is next touched upon, the affection in the male being especially remarkable by the permanence and tenacity of the symptoms which characterize it. The details of three typical cases of hystero-epilepsy in the male are presented, and the striking resemblance between these and the corresponding cases observed in the female is pointed out.

In following chapters, several interesting cases of brachial monoplegia, clearly hysterical in their nature, though following traumatism, are given. In one of these patients, besides the brachial monoplegia, which pertained to sensation and motility and the muscular sense, there was diminution of hearing, of smell, and of taste on the same side, contraction of the visual field, monocular polyopia, anæsthesia of the upper pharynx, and well-defined hysterogenous patches. The production of monoplegia of a member by hypnotic suggestion is shown (Chap. XXII); similar means are employed to cause it to disappear. These hysterical paralyses are sometimes limited to a part of a member, leaving intact the rest of the limb, in which sensation, motility, and tendinous reflexes are normal, as in Charcot's patient, Greuz, where, with complete paralysis above the wrist, most of the hand was normal in respect to innervation.

One point is clearly brought out by Charcot's observations: despite the high expectations that have of late been entertained respecting the utility of hypnotization as a therapeutic means in these obscure and often most intractable forms of paralysis, and despite the fact that some remarkable cures thereby affected have been recorded by Bernheim, Richet, and others, there seems really to be but a very limited number of cases, either in the male or female, that are actually amenable to hypnotic influence, or to any permanently beneficial results therefrom. It is easier, as Charcot shows, to produce at will in the hypnotic subject all the phenomena of hysterical paralysis (loss of motility and sensibility, analgesia, abolition of the muscular sense and of the tendinous reflexes) than to unmake a paralysis already existing, and the expression (it may be) of a dynamical cortical lesion of long standing.

Two chapters in the work alluded to are devoted to the consideration of hysterical coxalgia in the male subject, as illustrated by a remarkable case which is shown to be quite in harmony with the observations of Brodie, Coulson, and others respecting hysterical affections of the joints.

The subjects of hysteria are not always persons of seemingly delicate, "neuropathic" organizations, and some of Charcot's patients appeared to be remarkably robust. The same may be said of one of Dr. Joseph's patients (Landeck, Germany), as reported in the *British Medical Journal*, August 29, 1885. This patient "was a robust horse-dealer," father of a large family. He "caught cold," and aphonia followed. A little later clonus was complained of, and then he began to have convulsive attacks, without loss of con-

¹ *Leçons sur les Maladies du Système Nerveux*, t. III.

sciousness, but with loss of the power of speech. He had "globus" and "hyperæsthesia over the interscapular region, the lower cervical and upper dorsal vertebrae, but not in the iliac region." One of McIntosh's patients, characterized by "general hysterical hyperæsthesia," was a robust negro, fifty years of age.

The subject of hysteria in soldiers has lately been made the subject of an interesting monograph by Emile Duponchel, and Dr. A. T. Ozeretskovsky describes in the *Russian Medical Review* a whole series of cases of hysteria occurring in soldiers, presenting nearly all the phenomena usually associated with this affection as it occurs in females — dumbness, deafness, deaf-mutism, various disturbances of vision, spasms and paralyses, troubles connected with micturition, joint trouble, hysterical hyperpyrexia, etc. Predisposition and heredity played a large part in the etiology, and in some instances there was injury or "shock." The treatment of the hysterio-epileptic cases was always unsuccessful, neither hydropathy, electricity, nor narcotics appearing to exert any influence over the frequency or the severity of the attacks.²

Of late, the subject of hysteria in boys has attracted considerable attention. Dr. Savage has recorded a well-marked case in the *Journal of Mental Science* for July, 1885. At the meeting of the Cambridge Medical Society, June 1, 1883, as reported in the *Lancet*, Drs. Bradbury and Ingle reported cases in which, in quite young boys, the usual hysterical stigmata were pronounced.

Dr. H. Schmidt, of Bremen, has made a careful study of the subject of hysteria in children, and from several cases occurring under his own observation, in addition to the information gained from an examination of the literature of the subject, he draws the following inferences: (1) Cases of marked hysteria occur in children of both sexes; (2) hysteria is, however, a rare disease in the earlier years of life; (3) the basis of hysteria may be either anæmia or chlorosis, or "acquired nervousness"; (4) mild cases are amenable to treatment by a merely psychological regimen. The main therapeutical indication usually consists in the improvement of a vitiated constitution.³

FRACTURE OF THE STERNUM REDUCED BY A COUGH.

THE JOURNAL publishes to-day two very interesting cases of fracture of the sternum from very widely separated portions of the country, in which the displaced fragments were replaced accidentally by a cough. In the first, attempts at replacement were futile, and were for the time abandoned, when the cough fortunately

restored the symmetry of the bone. In the second, attempts were still in progress, but without result, until the cough was accidentally added, when the fragments snapped into place. This result has also occurred in a case reported by Dubroca, as seen by him in the service of M. Polaillon. Whether a cough instituted for the sake of effecting such a restoration would prove equally effectual in future cases can be determined only by actual trial when cases present themselves, but it will doubtless occur to every one who reads these two accounts that a procedure which may prove a very valuable adjuvant in these cases has been neglected.

The force exerted from within outward by a cough is in common use in the examination of hernia, and is, in reality, well understood. That the force is a great one is readily seen when we consider that it sometimes is sufficient to break ribs. Dr. Gillette gives, in the *Union Médicale* of June 27, 1876, a case of a man of fifty-six, emaciated to the last degree by pulmonary tuberculosis, who sustained a fracture of the eleventh rib of the left side during a severe fit of coughing. The *Medical Times and Gazette* of November 3, 1860, quotes the case of a patient of M. Piffard who fractured a rib during a paroxysm of cough, "the result of a cold," though the patient was robust, and, save for the cold, in perfect health. The cough certainly deserves a trial in future cases of fracture or dislocation of the sternum before such cases are abandoned to nature, or the more radical operative means are resorted to.

MEDICAL NOTES.

—"The Story of a Star" is the title of a new novel by Dr. Benjamin Ward Richardson, of London, the prolific medical writer and author of the *Asclepiad*. The scene of the story is in the second century, and the plot deals with the final efforts of the Hebrew people for national independence.

—The result of a trial just concluded at Canton, N. Y., before Judge Kellogg, will have a salutary effect in checking the sale of one class of adulterated food. Two men, named Moon and Ackerill, were arrested for selling adulterated baking-powder in violation of the State food adulteration act. The indictment was for both for selling baking-powders that were inferior, adulterated, and injurious to health by reason of being made from alum, and for selling them under pretence that they were a wholesome cream of tartar baking-powder. A stubborn defence was made, the claim being set up that baking-powders were not articles of food, and that the powder the defendants were selling, which was known as Gillett's, was a standard article of trade, and that alum baking-powders inferior to it, like Davis's and others, were being sold by other dealers in the same town without complaint. The court held that baking-powders were articles of food within the meaning of the law, and the jury found the defendants guilty upon all the charges.

¹ Dr. Jaansen reports several remarkable cases of hysteria and hysterio-epilepsy occurring among Dutch soldiers. See *Boston Med. and Surg. Jour.*, Vol. CXVII., p. 541.

² *Jahrb. d. Kinderheilkunde*, April 5, 1880 (cited in the *Medical Record*, Vol. XXIII., p. 291).

The case has attracted much attention from being the first brought under the New York State food adulteration act against dealers in alum baking-powders. The result of the trial is to class such baking-powders as adulterated articles of food, and to make their sale illegal. There are many alum baking-powders put up in cans, under some name or brand, in addition to those sold in bulk, the sale of all of which cautious dealers will probably be unwilling to continue.

BOSTON AND NEW ENGLAND.

—Another gift of \$1,000 has been received by the Boston Medical Library Association towards the payment for the land recently acquired by it for its proposed new building. Owing to an inadvertence, we neglected to chronicle the fact, a few weeks ago, that Dr. Oliver Wendell Holmes had presented his entire medical library to the Association.

—From the quarterly report of the Hospital Cottages for Children, at Baldwinville, Mass., of which Dr. Everett Flood is Superintendent, it appears that, of the 42 patients, 26 are epileptic, and that under treatment, dietetic and medicinal, an improved condition is considered to have followed in every one of these cases, and in some the improvement reported seems to have been very remarkable. Of the epileptics, 11 are girls, and 15 boys. The other cases are as follows: 1 eczema, 1 paraplegia, 4 spinal caries, 1 feeble-minded, 2 chorea, 1 rachitis, 4 hip-joint disease, 1 infantile paralysis, 1 knee-joint disease. The cases having a discharge coming from carious bone, of which there are 4 (3 spinal, one hip), are reported to have all done unusually well; and one, the hip case, for whom but little hope could be entertained, has, under the combined advantages of an immovably fixed joint, the pure air, and plenty of koumiss, made a remarkable gain.

NEW YORK.

PREVENTION OF CHOLERA.

—Mayor Hewitt has addressed a communication to the chairman of the Committee on Finance of the State Senate respecting the future management of the quarantine station, in which he proposes that if the legislature is unwilling to appropriate a sufficient amount to insure its thorough efficiency, the charge of the establishment shall be transferred to the New York City Board of Health. In the course of his letter he says: "I invite your immediate attention to the subject because during the last summer there was very great danger of an outbreak of cholera in this port, and it is generally expected that, according to past experiences, there will be a repetition of the disease this year. The quarantine establishment is in a very dilapidated condition, and the appliances are totally inadequate to deal with the danger of such an outbreak as we fear. Under the circumstances I feel it to be my duty to impress upon the legislature the necessity for action, and for the appropriation of a sum of money sufficiently large to put the establishment in a thoroughly efficient condition. It is es-

timated that about \$200,000 will be required for this purpose. This sum, although large, would be trifling compared with the pecuniary damage that would accrue to the business of this city and this State in case the cholera should be allowed to spread. I trust there will be no difficulty in having it provided in the usual manner by a State appropriation; but if it is deemed wiser to transfer the responsibility to the city of New York I am sure that public opinion here will justify the expenditure of any reasonable amount of money in order to protect the city from irreparable losses of life and property inseparable from the spread of this disease. The Board of Health of this city is so situated at the present time as to be able to take charge of the establishment, and to give it such direction and supervision as will protect the public from disease.

In case the legislature should see fit to transfer the quarantine establishment to municipal control it would be necessary, of course, that the fees should be paid into the city treasury, and there ought to be vested in the Board of Health sufficient power to recoup the expenditure which will be necessary in order to put it in good working order. As to how this result is to be accomplished I care very little, but the necessity for action is so great, and the feeling in this community so strong that I cannot too earnestly urge upon the attention of your committee the necessity for some action which will be adequate to meet the difficulties in the situation."

—The Linnean Society has organized a movement to erect a suitable monument to Audubon, the naturalist, in Trinity church-yard where he lies buried. It is to be in the form of an ancient Irish cross, which will be ornamented with animals and birds, and the bust of Audubon in relief.

BENJAMIN F. DAWSON, M.D.

—Dr. Benjamin F. Dawson died April 3d, of diabetes, from which he had suffered for several years. He was forty-four years of age, and a graduate of the College of Physicians and Surgeons, of New York, in 1866. While a student of medicine he served as acting assistant surgeon in the United States army during the year 1865. After graduation he practiced in his native city, devoting himself especially to gynecology and diseases of children. He soon won for himself an enviable reputation in these departments, and among the positions which he held at different times were the following: Lecturer on the Diseases of Children, in the Medical Department of the University of the City of New York, Professor of Gynecology in the New York Post-Graduate Medical School and Hospital, Assistant Surgeon of the Woman's Hospital, Attending Physician to the New York Foundling Asylum, and Pathologist to the New York Infant Asylum. He was also the founder of the New York Free Dispensary for Sick Children, and by his own efforts raised the funds by which this institution was maintained for a long series of years. He was a skilful and successful operator, and his powers of original invention were of a high order.

His ovariectomy clamp was used by gynecological surgeons of the highest eminence, and the Dawson battery is still regarded by many operators as the best in use for the galvano-cautery. Among his original operations one for prolapsus uteri has proved very successful.

Dr. Dawson made frequent and valuable contributions to medical literature, and was for many years an honored member of the New York Obstetrical Society and the American Gynecological Society. In 1868 he founded the *American Journal of Obstetrics and Diseases of Children*, and for six years continued to be its chief editor. In 1871 he edited the second American edition of Barnes's *Obstetric Operations*, published by the Appleton's, to which he, added considerable original matter. About three years ago he gave up his professorship at the Post-Graduate Medical School, which he had filled with distinguished ability, and retired from active practice on account of ill-health. Socially, as well, Dr. Dawson was a man of brilliant qualities, and he was widely known and esteemed.

—The agent of the Mediterranean line of steamers to which the *Britannia*, which recently arrived in port with small-pox on board, belongs, has cabled to the company in Europe not to allow any passengers to sail for America until they have been vaccinated.

PHILADELPHIA.

—The great event of the past week was the public dinner tendered Professor D. Hayes Agnew by some of his professional friends in commemoration of the fiftieth anniversary of his graduation in Medicine. Professor Da Costa was chairman of the committee, and presided at the dinner, which was given in the foyer of the Academy of Music on the 6th inst. Among the two hundred or more who were present were many prominent members of the profession from other cities as well as from our own. L. A. Sayre, Hunter Magnire, J. S. Billings, C. R. Agnew, J. Ford Thompson, R. F. Weir, Chas. C. Lee, and Alfred Stillé, Weir Mitchell, Joseph Leidy, William Pepper, J. G. Morton, S. W. Gross were observed around the handsomely-decorated table. The guests were seated at seven o'clock, after grace by Rev. J. S. MacIntosh. After the *ménu* had been rendered free justice, the chairman proposed the health of the honored guest of the evening, and gracefully referred to leading events in his career, and especially to the services rendered by him when summoned to the bedside of the wounded Chief Magistrate of the nation.

When the applause which greeted the rising of the venerable professor had subsided, Dr. Agnew said that had it been the pleasure of his friends a less conspicuous demonstration of their good-will would have been more in consonance with his feelings and taste. He regarded it as a great distinction for any man, in whatsoever sphere of life he may move, to win the confidence and esteem of his fellows. This mark of respect tendered him this evening was profoundly realized and appreciated. He had come to this city thirty-five years ago in order to gratify his taste for

studying anatomy. The scene of his early labors was the Philadelphia School of Anatomy, where so many who afterwards became leaders in the profession had worked — Godman Webster, Joseph Pancoast, Allen, Ganetson, Henry H. Smith, Ellerlie Wallace, Francis Gurney Smith — it was a veritable school of the prophets. He continued: "Here summer and winter, night and day, with rarely a vacation. I studied the mysteries of this wondrous frame, lovingly and with enthusiasm, and notwithstanding the opposition of the two great medical schools, drew around me a class that was only limited to the capacity of the building. These were the happiest days of my life. The anatomical odors of those dingy old rooms were to me as sweet as those of Araby. I loved it so that when I was induced to become Demonstrator of Anatomy in the University of Pennsylvania I did so with reluctance. It was here that I formed the friendships which, like hooks of steel, have bound me to men of every part of the country, and not a few across the sea.

"To Dr. Henry H. Smith and Dr. John L. Ludlow more than to all others combined, are we indebted for the restoration of clinical instruction in the Philadelphia Hospital. For twelve years, save a short interregnum, Dr. Smith and myself taught surgery in the hospital. For eleven years I was on the staff of the Pennsylvania Hospital, until the inauguration of a policy that compelled me to resign. I have never hesitated to turn my back on any proposition or place, no matter how tempting, the acceptance of which would compel a surrender of my convictions. It has been my fortune to fill many places of dignity in the profession, but the principal satisfaction it gives me is that I never schemed or planned for any of them. When the end shall come, I shall feel that I have had more than I deserved, and among the choicest recollections will be the memory of this assemblage."

Dr. Sayre made a characteristically witty speech in reply to the toast of "Our Visiting Physicians," and Dr. Weir Mitchell read the following poem, written for the occasion:

MINERVA MEDICA.

A golden wedding; fifty earnest years.

This Spring-tide day from that do sad'ly part,
When, 'mid a learned throng, one shly grave-lad,
Half-conscious, won the Mistress of our Art.

Still at his side the tranquil goddess stood,

Unseen of men, and claimed the student boy,
Touched with her cool sweet lips his ruddy cheek,
And bade him follow her through grief and joy

"Be mine," she whispered in his startled ear.

"Be mine to-day, as Paré once was mine;

Like Hunter mine, and all who nobly won

The fadless honors of that shining line.

"Be mine," she said, "the calm of honest eyes,

The steadfast forehead, and the constant soul.

Mine the firm heart on simple duty bent,

And mine the manly gift of self-control.

"Not in my service is the harvest won

That gilds the child of barter and of trade;

That steady hand, that ever-pitying touch,

Not in my helping shall be thus repaid.

"But I will take you where the great have gone,

And I will set your feet in honor's ways;

Friends I will give, and length of crowded years,

And crown your manhood with a nation's praise.

"These will I give, and more; the poor man's home,
The anguished sufferer in the clutch of pain,
The camp, the field, the long, sad, waiting ward,
Watch for your kindly face, nor watch in vain;

"For as the sculptor years shall chisel deep
The lines of pity 'neath the brow of thought
Below your whitening hair the hurt shall read
How well you learned what I my best have taught."

The busy footsteps of your toiling stand
Upon the noisy century's sharp divide,
And at your side, to-night, I see her still,
The gracious woman, strong and tender-eyed.

O stately Mistress of our sacred Art,
Changeless and beautiful and wise and brave,
Full fifty years have gone since first your lips
To noblest uses pledged that forehead grave.

As round the board our merry glasses rang,
His golden-wedding chimes I heard to-night;
We know its offspring: in a hundred towns
His pupil children bless his living light.

What be the marriage-gifts that we can give?
What lacks he that on well-used years attends?
All that we have to give are his to-day, —
Love, honor and obedience, troops of friends.

An ode was also read by Dr. Thomas Wistar, which was a pleasant feature of the evening.

It is intended to hold an Agnew Jubilee on the 24th inst., at the University of Pennsylvania, in order to allow a larger number to participate than could be seated at a formal dinner. A portrait of Professor Agnew will be painted and placed in the Hall of the College of Physicians.

— John B. Hamilton, Supervising Surgeon-General of the Marine Hospital Service, delivered the annual oration this year before the Alumni Association of the Medico-Chirurgical College on the 5th inst. A reception was given in his honor on the same evening. The seventh annual commencement was held on the following day, twenty men receiving the degree of doctor in medicine.

— The sixty-third annual commencement of the Jefferson Medical College was held last week, a class of 188 students being graduated. Prof. Austin Flint, of New York, delivered the annual oration before the Alumni Association of the Jefferson College, and was tendered a reception at the Bellevue later in the evening.

— The following minute has been sent to the city authorities:

Whereas, The College of Physicians of Philadelphia have learned that it is proposed to furnish the citizens of Philadelphia with illuminating gas, consisting of two parts of coal-gas and one part of water-gas, a mixture of which would probably contain at least about fifteen per cent. of carbonic oxide, and

Whereas, In the opinion of this College, the use of any illuminating gas which contains more than ten per cent. of carbonic oxide would be attended with very grave risk to the health and life of the citizens of Philadelphia; therefore be it

Resolved, That the Mayor of Philadelphia is hereby petitioned that, if in his opinion it be necessary to use water-gas in connection with illuminating gas, great care be taken to render it certain that the mixture shall at no time contain more than ten per cent. of carbonic oxide.

Miscellany.

MULTIPLE SALIVARY CALCULI.

THE *British Medical Journal* reproduces from the "Proceedings of the Stitchizry Medical Society," Vol. I, 1887, p. 68, a report by Dr. Nikolai J. Moiseff, of the case of a retired major-general, aged seventy, who sought his advice on account of incessant profuse salivation, pain on deglutition, and sublingual swelling of several years' standing. An oblong, hard elevation was found along the course of Bartholin's duct, which, even on slight pressure, gave the finger a distinct grating sensation. The duct was considerably distended along its whole course, and contained three salivary calculi lying in close contact. The nearest and smallest concretion, of the size of a big pea, was easily removed with forceps, but the other two could be extracted only after slitting up the duct, since they were considerably larger, especially the deepest one, which measured two centimetres in length and one in breadth, and, in addition, was intimately adherent to the gland substance; it resembled a bird's bill in shape. When dry it weighed 2.2 grammes, and consisted of a comparatively hard and compact nucleus, with a spongy, friable outer capsule. The smallest calculus was of pyramidal form, of spongy consistence, and grayish-yellow color; while the middle one was quadrangular, with rounded angles, and of a distinctly laminated structure. The total weight of the dried calculi was thirty-eight grains. The wound healed well in a week. Dr. Moiseff has been unable to find another recorded instance of multiple calculi simultaneously present in the same salivary duct.

THE DIRECTION OF SCRATCH-MARKS MADE BY THE NAILS ON THE SKIN.

THE medico-legal importance attaching to the direction of nail-scratches on the skin was illustrated in the case of Pranzini, the Parisian murderer, whose crime and its detection are thus described by the *Dublin Journal of Medical Science*:

The murder occurred at the Rue Montaigne, Paris, and the victims were a celebrated *demimondaine*, who, along with her maid and maid-servant, was found murdered in their apartments under circumstances of great cruelty. Their throats had been cut after a severe struggle, and their bedding and the walls of the apartments in their vicinity were copiously bespattered with blood. The unfortunate chief victim was the possessor of jewelry and other valuables to the extent of some thousand pounds, presumably the motive of the murder. These, however, were in an iron safe, and as the murderer, who was evidently single-handed, could neither open this nor carry it away, he had to leave without the wages of his crime. The key was subsequently found concealed in a wardrobe. A man named Pranzini, a follower of the victims, was arrested upon suspicion, but the closest examination of his clothes, both those which he had worn on the evening of the crime, and those found at his residence, showed no trace of blood. This was relied upon as a strong point in the defence, but Dr. Brouardel, the *Médecin légiste* engaged in the matter, recalled the fact that in the next apartment was found a toilet-stand, upon which was a large basinful of ensanguined

water, as if some person stained with blood had washed therein. As none of the three victims had presented the appearance of having done this, Dr. Brouardel conceived the idea that the murderer had, on entering the apartments, undressed himself, had committed the crime in a state of nudity, had then carefully washed himself of its traces, and had finally, all being completed, resumed his clothes, of course free from all sanguineous stains. Dr. Brouardel now demanded from the *juge d'instruction* an authorization to examine Pranzini totally undressed, and on this being accomplished, found a long, tearing scratch (*estafilade*) extending down the front of his right thigh. Interrogated upon this, the prisoner said that he had been attacked by a severe itching in the part, and had torn himself in relieving it. Being invited to repeat the gesture, he did so, scratching himself from the knee towards the body, when the medical expert showed that the tear had been produced by nails, or at all events, some sharp body, acting from above downwards in the direction of the knee, as was shown by the pointed fragment of epidermis projecting upwards from the lower end of the wound. The expert's hypothesis is that when the assailant approached one of his victims, with the weapon in his right hand, and with his right side next to her, she inflicted the injury with her nails. Questions of blood-stains on clothing have frequently formed important evidence in murder trials; but the present is probably the first

instance of an ingenious plan having been adopted to escape clothing-stains, and of its being defeated by an accident developed by the acuteness of the medical expert. Pranzini was convicted, without extenuating circumstances, and was sentenced to death by the guillotine.

Correspondence.

THE DIAGNOSIS OF ADENOID VEGETATIONS.

Boston, April 6, 1888.

MR. EDITOR.—In Dr. Hooper's most excellent paper on Adenoids in Children, recently published in this *Journal*, I find no mention of a symptom which is sometimes of value, and which has been quite noticeable in some of my cases, and that is, the impossibility of blowing the nose. This sign can, of course, have no significance in very young children, but after the age of five or six years most children learn by themselves, or can be taught, to blow the nose fairly well. Where the post-nasal space is filled with these vegetations the child is unable to force a current of air out through the nose, and it is often necessary for the physician to wipe out the nose anteriorly with cotton wool on an applicator to get a look at the inside of the nose, which had been filled with secretion, which the child had been unable to remove. The ineffectual attempts of the child to blow the nose when the supply of air from behind is cut off have been to me of special diagnostic value in children over five or six years.

Yours truly,

JOHN W. FARLOW, M.D.

Deaths reported 2,148; under five years of age 754; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 279; acute lung diseases 386; consumption 317; diphtheria and croup 97; scarlet fever 41; measles 25; typhoid fever 23; diarrheal diseases 25; whooping-cough 24; cerebro-spinal meningitis 17; erysipelas 10; malarial fever six, small-pox five, peripneumonia four. From measles, Baltimore and District of Columbia nine each. New York three, Philadelphia two, Milwaukee and Gloucester one each. From diarrheal diseases New York 11, Philadelphia five, Boston, Nashville and Fall River two each, District of Columbia, Cambridge and Fitchburg one each. From whooping-cough Philadelphia seven, Boston six, New York four, Baltimore three, Philadelphia two, Chelsea and Taunton one each. From erysipelas, New York four, Philadelphia two, Baltimore, Boston, Worcester and Lowell one each. From cerebro-spinal meningitis, Lowell six, New York three, Milwaukee and Lynn two each, Philadelphia, District of Columbia, Worcester and Fall River one each. Malarial fever New York and Philadelphia, two each, Baltimore and Nashville one each. From small-

pox New York four, Philadelphia one. From peripneumonia, Milwaukee two, Baltimore and District of Columbia one each.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending March 17th, the death-rate was 20.3. Deaths reported 3,056; infants under one year of age 812; acute diseases of the respiratory organs (London) 458; whooping-cough 148; scarlet fever 49; measles 46; fevers 33; diarrheal 20; diphtheria 33; small-pox (Sheffield 18, Huddersfield, Manchester and Bristol two each) 24.

The death-rates ranged from 12.8 in Leicester to 31.6 in Blackburn; Birmingham 16.5; Bolton 24.4; Bradford 22.7; Halifax 24.1; Hull 15.5; Leeds 19.5; Liverpool 20.1; London 19.5; Manchester 24.7; Newcastle-on-Tyne 20.9; Norwich 26.2; Nottingham 19.4; Sheffield 21.2; Sunderland 22.2.

In Edinburgh 17.3; Glasgow 27.0; Dublin 29.0.

The meteorological record for the week ending March 31, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.			
		Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Daily Mean.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Duration, Hrs. & Min.	Amount in Inches.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDED APRIL 7, 1888.

ARMSTRONG, S. T., passed assistant surgeon. Granted leave of absence for fourteen days. March 21, 1888.

BRATTON, W. D., passed assistant surgeon. Promoted and appointed passed assistant surgeon from April 6, 1888. April 2, 1888.

SOCIETY NOTICE.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—The Annual Meeting will be held in Roberts Hall, 710 Main Street, Waltham, on Wednesday, April 18, 1888, at 1 o'clock P.M. The annual address will be delivered at 2 o'clock, by Dr. H. F. Walcott of Cambridge. The Censors of the Society will meet at the same place at 12.30 A.M., of the same day, to consider applications for admission to the Massachusetts Medical Society. Dinner will be served at 3 o'clock, for which probably no assessment will be made. Telephone call, 7635.

WALTER ELA, Secretary.

CAMBRIDGE, April 11, 1888.

OFFICERS OF THE NEW YORK NEUROLOGICAL SOCIETY.

At the Annual meeting of the New York Neurological Society held April 3d, Dr. George W. Jacoby was elected President. Drs. C. L. Dana and M. A. Starr, Vice-Presidents, and Dr. B. Sachs, Recording Secretary.

WILLIAM B. GOLDSMITH, M.D.,

The New England Psychological Society, having learned the painful news of the death of a highly valued and beloved member, Dr. William B. Goldsmith, Superintendent of the Butler Asylum at Providence, R.I., recalls with a deep sense of its great loss, his high character, exceptional ability and refined and genuine nature.

Resolved, That such has been the influence of his opinion, based upon his solid attainments and great devotion to his work, that broader views of the treatment of the insane and deeper insight into mental disease, have come to many of us, his fellow-workers.

Resolved, That by his death is lost a tried and considerate friend, a judicious and helpful counsellor, and a courteous and cultivated associate.

Resolved, That the Secretary be requested to communicate these resolutions to the family of our deceased friend, and to extend to them our profound sympathy in their sorrow.

H. H. STEDMAN, M.D. }
THOS. W. FISHER, M.D. } Committee.
C. P. BANCROFT, M.D. }

WALTER CHANNING, M.D., Secretary.

BOOKS AND PAMPHLETS RECEIVED.

Transactions of the Ninth Annual Meeting of the American Laryngological Association, held in the City of New York, May 26 to 28, 1887. New York: D. Appleton & Co. 1888.

A Manual of Diseases of the Nervous System. By W. R. Gowers, M.D., F.R.C.P., Assistant Professor of Clinical Medicine in University College, London. American edition, issued under the supervision of the author, and containing all the material of the two-volume English edition, with some additions and revisions. With 341 illustrations. Philadelphia: P. Blakiston, Son & Co. 1888.

AN ABUSED AND NEGLECTED REMEDY.

BY SAMUEL S. WALLIAN, A.M., M.D., NEW YORK.

THE history of every novelty, innovation or advance in the line of therapeutic measures, is marked and punctuated by a succession of vicissitudes and experiences so uniformly resembling each other, in general features, that a student of medical history might forecast them, in any given case, with greater accuracy than is shown in the average predictions of the Signal Service Bureau.

First, there is the original enthusiast, who, sooner or later, multiplies,—possibly by the process of fissiparism,—into a more or less respectable corporal's guard of camp-followers, who soon succeed in earning the slangy modern title of "cranks." Goaded by opposition and unkind criticism, they take refuge in an almost vituperative over-statement of facts, and over-estimate of possibilities, call down upon themselves merited ridicule and persecution, and this, frequently culminates in abuse and ultimate professional ostracism. This is much less true at the present day than at any former time in the history of medicine. Never was the profession so ready to greet new assumptions with respectful tolerance, and to give them ample opportunity to demonstrate their worth or worthlessness, as now. Instance the fairly epidemic furor with which Bergeon's unnatural and irrational treatment of phthisis swept over the country. Instance, also, the stenocarpine faze.

Again, each new theory, vaunted specific and therapeutic hobby suffers its period of decadence, following a brief heyday of novel popularity, and regardless of its merits or want of merit, it falls into desuetude, if not into contempt. If its claims be based on chemistry, common sense, or clinical experience, it eventually emerges from its undeserved banishment, and is sooner or later revived or re-discovered; after which old assumptions are revamped, fresh experiments are conducted, and, finally, some renowned clinician or acknowledged authority sets the seal of success on it, forever, by adopting it as his own god-child.

This line of thought was suggested by the discussion of the use of oxygen gas in pneumonia, by members of the New York State Medical Society, recently reported in these columns. Of all the therapeutic measures now being brought into more general use, oxygen is certainly one of the most promising. At the same time, there is not a remedy in the whole materia medica which has had to run the gauntlet of so much direct and indirect abuse, or of so much professional bungling.

First, it has been hawked by quacks, until, in many professional minds, its very name smacks of charlatanism.

It has been, and still is, used by honest and well-meaning physicians, in such an inaccurate and unscientific manner, that it is fairly astonishing when any but negative, unsatisfactory, or even disastrous results are reported.

As an example of the first, it is only necessary to instance any one of several firms, which, for years, have advertised as extensively as any of the leading nostrum concerns of the country. Dispensing as they do an almost inert and quite inexpensive solution of therapeutic nothings, at conscienceless prices; cunningly and unstintingly prostituting the columns of

the religious press; these parties are unscrupulous in assertion, and hesitate at nothing which will advance their prime object,—the wringing of money from credulous dupes, who are always quite willing to be deluded by gilded and glib-tongued sophistry.

To illustrate what I mean by inaccurate and unscientific manner of exhibition, it will be sufficient to merely advert to the average methods of administration in vogue, even among practitioners of eminence, and those who are vaguely conscious of its presumed value, and conscientious in their efforts.

Suppose it is a critical case of pneumonia,—the patient panting for breath, cyanosis increasing, the non-aerated blood constantly growing darker and more sluggish, every moment adding to the suffering of the patient and the consternation of the friends. The medical attendant realizing that oxygen would meet the emergency, hurriedly sends to the nearest calcium light company for a "tank" of the gas. It arrives, looking very much like a sheet-iron hot-water reservoir. Of its purity or impurity, or the per cent. of chlorine present, he makes no question. Nor has he ever read up, even the meagre literature of the subject, much less questioned as to the devitalizing effect of compression, on even the purest gas. Unaccustomed to the technique of oxygen apparatus, he is puzzled to know how to bring the vitalizing gas into contact with the carbonized blood of his semi-asphyxiated patient. However, he turns on the gas, (at a pressure of two hundred or three hundred pounds to the square inch), liberating five or twenty gallons, he hardly knows which, and watches the results. Perhaps there is a measure of relief; but more likely the result is negative, if not positively damaging. What other remedy could withstand such hap-hazard manipulation, amounting to mere guess-work!

The therapeutic employment of oxygen gas is no longer of questionable utility. It is gradually commanding attention in the highest professional circles, and is being recognized as a desideratum in numerous conditions which have hitherto proved tedious or wholly unmanageable. The chief sources of hindrance to its more general employment have been the professional carelessness referred to, and the general lack of facilities for procuring a prompt supply of the agent, in convenient form, and of a quality sufficiently pure for prolonged clinical exhibition. The commercial gas available is not fit for medical purposes, on account of chlorine and other impurities, which the manufacturers find it difficult to remove, and which are not particularly objectionable in the production of oxy-hydrogen light, for which it is chiefly used.

But it is not necessary to use impure or questionable gas. The process for evolving pure oxygen is not complicated, and may be conducted without the aid of expensive apparatus by those who are not particularly apt in chemical manipulation. Familiar as it is, perhaps its concise repetition may assist some experimenters who have never attempted it, or whose recollections of the laboratory have been dimmed by time.

The best formula, for practical purposes, is that suggested by Fresenius:

R. Potass. chlorat.	lbs. iv.
P. Manganesi dioxide.	lbs. i.
P. Ferri carb. prec.	3ij.

M.

S. To be well mixed and triturated, avoiding violent friction, lest an explosion be produced. (With reasonable care, the liability to this accident is very slight.) The prepared material should be ther-

oughly desiccated by being exposed to moderate heat in an open oven, or by means of a chemical drying chamber. Store in any receptacle which will protect it from moisture until wanted for use.

The best retorts are made of either brass or iron. Copper oxidizes more rapidly, besides requiring an increased degree of heat. The conical shape, with broad bottom, is much superior to the old-fashioned flat or pear-shape, the evolution of gas from the latter being tumultuous, and less under control. For making more than thirty or forty gallons at an effort, the cylindrical form of retort is still more preferable. With the latter form, the process is entirely under control.

A portable form of apparatus is now being made in New York which uses cylindrical retorts of small size made from brass, and connected by means of a nipple and friction-joint. An important improvement has also been made in the form of wash-bottle tube. It consists in expanding the lower or submerged end of the tube into a hollow bulb having a number of minute perforations, through which the gas is forced to escape in exceedingly fine bubbles, thus insuring its more perfect contact with the washing or purifying fluid.

I have used this unique and ingenious device in my practice for some months with the best of satisfaction. It renders the gas available hereafter to a large number of practitioners who would forego its use, rather than cumber themselves with the larger and more expensive apparatus. Its capacity, at each operation, is sufficient for any ordinary emergency, and the process can be repeated every fifteen minutes, consecutively if desired. Compact as it is, the gas evolved is, if anything, more perfectly purified than is ordinarily accomplished by the usual laboratory appliances. It is also cooled and desiccated by being passed through a deep layer of anhydrous calcium chloride. It can thus be administered to the patient at a temperature approaching the freezing point, if desired. This gives all the effect of compressed gas, with none of its drawbacks.

A word about compressed gas. In my experience, it is decidedly deteriorated by the process of compressing it. Whether the change is one of molecular arrangement, or what it is, probably cannot be accurately determined. Whatever it is, the compressed gas is practically or partially devitalized. In comparison with nascent or fresh-made and uncompressed gas, it is, to use a commercial expression, not worth half-price. No physician who has used only commercial, compressed oxygen gas can give an intelligent opinion as to the real merits of the treatment. There is more difference between the two conditions of the gas than between fluid extracts made from roots and barks, inert or changed from age, and those prepared from freshly-gathered material.

Professor Dewar, of the Royal Institution, London, has announced the possibility of preparing solid oxygen. The experiment, although ingenious, is, for the above reason, without clinical significance.

Beddoes was the first oxygen "crank." Hill was a faithful disciple, but lacked originality. Both were over-enthusiastic, and, considering the crude appliances with which they were obliged to work, and the crude state of medical science at the time, it is almost incredible that they should have avoided prosecution for malpractice.

Fourcroy, who was a contemporary of Priestley and Lavoisier, was the first scientist to reduce the experiments with oxygen, as a remedy, to something

like system. His eminence, both as chemist and physician, gave some weight to his conclusions, which are thus tersely stated: He asserts that he "had witnessed good effects from inhalations of oxygen in the chlorosis of young girls, in the scrofulous affections of children, in humid and chronic asthma, in abdominal obstructions, in hypochondria, in commencing rachitis, and in those obstinate dyspepsias accompanied by pallor of the skin and general debility."

To this original synopsis of the therapeutic promise of this agent, the desultory experimentation of the past three-quarters of a century has added little that is vitally important.

In it we have a key to vaster and more important possibilities than most of us have yet dreamed of. In a future paper I may venture to report some individual experiences I had during the last few years, which emphatically corroborate all that is asserted by the eminent French physicians.

A CASE OF RETINITIS PIGMENTOSA TREATED ELECTRICALLY.¹

BY MYLES STANDISH, M.D.,

Ophthalmic Surgeon to Out-Patients, Carney Hospital; Assistant Ophthalmic Surgeon, Boston City Hospital; Instructor in Ophthalmology in the Boston Polytechnic, etc.

I AM well aware that to report the result of the treatment of a single case of any disease, and to draw deductions therefrom as to the efficacy of the method of treatment, is a rash proceeding, and I would not occupy the time of the Society by reporting this case except for the fact that it is one of several cases reported at the last meeting of this Society by Dr. Hasket Derby in a paper which excited considerable discussion at that time.

The patient was a woman, thirty-three years of age. She had myopia of 1.50 diopters in each eye, and had worn correcting lenses since she was seventeen years old. Her parents were not relatives. She was the only child of her father's first marriage, and had several half-brothers and sisters who had never had any trouble with their eyes. Several members of her mother's family were "near-sighted."

When first seen by me, on the 14th of April, 1886, she had noticed an increasing failure of vision for the previous three years, which had increased very rapidly in the three months previous to her visit to me. Her night-blindness had recently become so great that she could no longer go on the street after night-fall with safety. The ophthalmoscope showed a considerable number of the characteristic star-shaped spots of retinitis pigmentosa in the periphery of the fundus in each eye. Her vision was: right, $\frac{1}{20}$; left, $\frac{1}{20}$.

The field of vision did not extend over 20° in any meridian in either eye.

The only treatment employed in this case was the continuous electrical current. The positive pole was placed upon the closed eyelid, and the negative pole on the brow or temple. The strength of the current used was only such as could be comfortably borne, and has generally been derived from four or six cells of a Störer's battery.

The current has been passed in this manner for five minutes at a time at intervals of several days.

For the last ten months there has been a uniform

¹ Read before the American Ophthalmological Society, 1887.

interval of five days between the sittings. The patient has not been restricted in the use of her eyes while under treatment, and has used them constantly for fine work.

For the fifteen months that she has been under treatment there has been a steady improvement both in central and eccentric vision from the commencement up to the present time, except as hereinafter stated. These exceptions are, first, that there has been no improvement of vision for the last three months, although under treatment during that period; and, second, that in the summer of 1886, after the patient had been under treatment for four months, she went out of the city on a vacation, and was absent for six weeks, during which period the electricity was omitted, and upon her return it was found that her vision had fallen somewhat, both centrally and eccentrically, but the loss did not exceed a quarter of what she had previously gained. Her present vision is: right, $\frac{1}{2}$; left $\frac{1}{3}$. The present horizontal diameters of the fields of vision are: right, 75° ; left, 70° ; and the vertical diameters are: right, 70° ; left, 68° . This rather startling result has been verified by repeated examinations. The fields of vision have been taken with great care in the earlier, as well as the latter periods of observation, upon a perimeter, at noon on a clear day, with the perimeter facing the light, and at the same distance from the window at each trial. The objects used in determining the areas of the fields have been pieces of white paper one centimeter square. In testing central vision, the test-types have been changed from time to time, to avoid the danger of making too high a record by the use of familiar letters. Some ophthalmoscopic changes have taken place while the patient has been under treatment, but these changes have been confined to a widening out of the prolongations of each patch of pigment, so that they do not now present such characteristic bone-corpuscle-like shapes as they did when first seen. No new patches of pigment have appeared.

To argue from this case that all, or even a very considerable number of cases of retinitis pigmentosa would be similarly benefited by the use of electricity would be manifestly absurd; but that such an improvement in central and eccentric vision should happen to any case of retinitis pigmentosa, either with or without treatment, is a noteworthy fact, and one that should draw our attention to the circumstances of that particular case.

We have present in this case, besides the constant treatment during a period of fifteen months, several other peculiarities. It came on fully as late in life as this disease ever develops; that is, if we may believe the patient's statement, at about thirty years of age, but did not progress very rapidly until the last three months before she came under observation, during which period, however, the onset of the disease was unusually rapid. Again, when first seen, the impairment of vision was very much greater than we should be led to expect by an examination of the fundus, from which it would appear that treatment was begun while the disease was yet in its active stage, preceding the visible deposition of pigment in the retina.

From these considerations it would seem that, in so far as one case is capable of teaching anything, that when a case of retinitis pigmentosa is seen in its earliest stages, or when there is a sudden exacerbation

of the disease, as evidenced by diminution of the functions of the eyes, that a trial of galvanism should be made.

PARALYSIS OF THE POSTERIOR CRICO-ARY- TENOID MUSCLE FROM SWALLOWING A MARBLE.¹

BY E. A. KEMP, M.D., DANVERS, MASS.

EDWARD B., age six years, had always been well up to June 27, 1886, with the exception of having the usual diseases of childhood. On the 27th of June he had taken a walk with his father. On their return, when about ten rods from their house the father noticed that he was more quiet than usual, and seemed to be trying to swallow something. The father asked him what the matter was? he answered, "I have swallowed some grass." The father noticed that he looked quite pale, and appeared as though not fully conscious. He took him in his arms and carried him to the house. The extremities were quite cold. He seemed listless but without pain. He remained much the same for two days, talking to no one and merely answering a few questions that were asked him. The mind seemed pretty clear most of the time. He had a good deal of headache during the time he was confined to the bed; the pain being mostly on the left side at the back of the neck. There was noticeable in the breathing a slight dyspnea with some hoarseness in coughing. He had no appetite, and rested poorly during the night. Nine days before this attack he was accidentally bit with a stone on the left side of the head near the neck. He cried a good deal at the time, and for two or three days complained much of soreness; but it did not seem to trouble him much a week after he was taken sick; then he complained a good deal of the left side of the neck. There was considerable stiffness, and the head was slightly drawn to one side. He remained in this condition for over three weeks. Improvement was gradual, and at the end of that time the patient was able to be up and dressed. About two weeks later it was noticed that he breathed like a child with enlarged tonsils. He was worse at night; in fact, he was much worse when asleep. The parents were told that it was asthma, and were advised to take him to the mountains. Accordingly about the last of August, he was taken to Vermont for a change of climate, but instead of improving, he grew worse. The breathing was very good during the day, or at any time while awake, but at night, while sleeping, it was so noisy that it disturbed the whole household, and at times kept them from sleep. The history of the case thus far was gleaned from the parents. It had been diagnosed as asthma, laryngitis and bronchitis.

I first saw the patient on the 14th of September. I found him dressed and quite cheerful. He seemed to enjoy his play at times. He was paler than usual, had lost a good deal of flesh, and had very little appetite. He was very irritable and fretful at times. The breathing was pretty good with the exception of some dyspnea during inspiration, which symptom was greatly increased during any active exertion. He had frequent paroxysms of coughing while sleeping at night. The noise of breathing was almost beyond description, and could be heard all over the house; even members of the family who occupied the third story

¹ Read before the Essex South Medical Society, November 1, 1887.

during the night, were kept awake by his stridulous breathing, the boy being on the first floor. Upon inspection with the laryngoscope there was no catarrhal inflammation of the mucous membrane. The vocal chords during inspiration, instead of being abducted, remained nearly approximated; the opening of the glottis forming a very acute isosceles triangle, the aperture varying from one to two lines. In fact, by pressure of the air on their upper surfaces the vocal chords would be brought closer together during inspiration. They seemed to act as valves which are closed by the weight of the atmosphere upon their wide upper surfaces pressing them against each other; hence the inspiratory stridor and dyspnoea. Thus the order of the movements of the chords was changed. In the normal condition the glottic aperture is wide in inspiration, and narrow in expiration; in this case narrow in inspiration, and, while not wide, at least wider in expiration than in inspiration.

Now the crico-arytenoidei postici muscles in action separate the vocal chords, and open the glottis by rotating the base of the arytenoid cartilages outward and backward, so that the anterior angles and the ligaments attached to them become quickly separated. They are then the abductors of the chords, while the crico-arytenoidei laterales are antagonistic; that is, they are the adductors. It can therefore be readily understood that with a paralysis of the crico-arytenoidei postici muscles, there should result the condition just described: a narrow glottis on inspiration. Being fully convinced that I had to do with a case of posterior crico-arytenoid paralysis, the question arose as to the cause, a question which I could not answer at that time. The case grew worse day by day, and I feared tracheotomy would have to be resorted to in order to give relief. On the night of the 20th of September, the child had a very hard time. The paroxysms of coughing were almost incessant, with very few intervals of relief. During the paroxysms it seemed almost as though he would strangle. He would clutch at his throat with both hands, saying, "I cannot breathe; I shall die." The parents were almost beside themselves, seeing the child suffering so much, with so little apparent prospect of relief. During the worst paroxysm, when it seemed as though he could not get his breath, he held his hand to his mouth and said "I have got it"; and in his hand was a marble which he had just spat up. This gave almost instant relief and he soon fell asleep and rested well for four hours. The dyspnoea was much diminished, while the stridor had not yielded as much.

This marble must have been impacted at the orifice of the oesophagus, where it pressed on the abductor muscles. After the rejection of the marble the patient commenced to improve slowly. His appetite returned and he gained in flesh. The dyspnoea and stridor yielded very slowly. It is now seventeen months since this patient was first affected, and to-day he apparently is perfectly well; but at times a slight hoarseness of the voice, which he did not have before this sickness, can be noticed.

The only case of a similar character which I can find on record, is one of Ott's, reported by Dr. Morell Mackenzie, of London, in which a piece of meat was impacted at this orifice, and though it remained only twenty-four hours, still the effect it had on the abductors was apparent.

When we take into consideration the action of the

different laryngeal muscles in health, and note their condition during a state of paralysis we can see that a correct diagnosis of this condition is not so very difficult. Given a patient who has a normal or almost normal voice, with freedom of expiration, but great inspiratory dyspnoea much increased on the slightest exertion and accompanied with great stridor in sleep, a trouble of the abductors must be suspected. Of all the muscles of the larynx, these are the most important so far as life is concerned, and no others give such prominent and distressing symptoms, when paralyzed.

REPORT ON MEDICAL CHEMISTRY.

BY WILLIAM E. HILLS, M.D.

ARSENIC.

It is well known that when organs containing arsenic undergo putrefaction a gradual diminution in the amount of arsenic takes place, owing to the formation of volatile compounds.

Hamberg¹ reports the following experiment. He added one gram of arsenious oxide to some finely divided organs, and placed the mixture in a flask. He found that the gases evolved during the putrefaction of the organs contained an abundance of arsenic. In the residue, after the evolution of volatile arsenical compounds had ceased (about nine and a half years) arsenic was found in the form of arsenic acid. The amount of arsenic present corresponded to 0.551 gram arsenious oxide. The gases evolved during this experiment were conducted through a four per cent. silver nitrate solution; but, although nearly one-half the arsenic originally present had been lost, only a small portion was retained by the silver salt. (That is, only a small portion of the arsenic was given off in the form of arseniuretted hydrogen, which has usually been assumed to be the principal form in which arsenic is given off under such circumstances. The greater portion of the arsenic must, therefore, have been evolved in the form of volatile organic compounds not decomposed by silver nitrate. Thus, perhaps, is explained the repeated failures to obtain any evidence of the presence of arseniuretted hydrogen in the air of rooms papered with arsenical wall-papers. While it is, on the whole, more reasonable to suppose that a majority of cases of arsenical wall-paper poisoning are caused by the inhalation or swallowing of arsenical dust, still certain cases seem to suggest that some more active arsenical compound may have been the chief agent in producing the symptoms. The formation of arseniuretted hydrogen has been suggested in explanation of such cases. But it must be acknowledged that it has not been satisfactorily proven that this compound is very liable to be formed under such circumstances. Hamberg's experiment in point of fact seems to show that it is *not* likely to be formed to any great extent even when the conditions are apparently the most favorable for its formation. It seems desirable under the circumstances that further experiments be made relative to the possibility of the formation of other volatile arsenical compounds in rooms papered with arsenical papers. — *Rev.*)

BISMUTH.

The application of subnitrate of bismuth to open wounds has frequently been followed by symptoms of

¹ Zeitschrift für Analytische Chemie, 1887, 6, p. 756.

poisoning — nephritis, stomatitis and enteritis. These effects are the more striking as large amounts can be taken by way of the stomach without injury. The symptoms provoked by preparations of bismuth have been attributed to metallic impurities; for example, to antimony, lead, and especially arsenic; but experiments of P. Dalché and E. Villejean² on guinea-pigs and dogs, seem to show that they are due in part, at any rate, to bismuth. In their experiments they administered subcutaneously the neutral nitrate of bismuth in a twenty per cent. solution with some glycerine. Four experiments were made, all resulting in the death of the animal. The following details of one experiment are given:

A dog weighing 4,800 grams received the salt for twelve days in doses gradually increased from 0.3 gram to 3. grams. On the fourth day he lost appetite and strength. Towards the end of the treatment there was an increased flow of saliva, and on the twelfth day he died, having lost two kilograms in weight. On the eighth day the discharges were dysenteric and mixed with blood and so continued until death. A few days before death bluish spots were observed on the gums about the molar teeth of the lower jaw, and two similar patches on the inner surface of the cheeks. By degrees the gums, lips and cavity of the mouth presented generally this blue appearance, which finally resulted in gangrene of the inner surface of the cheeks.

The authors determined the amount of bismuth in the various organs of one of the dogs, and found 2, 6, 6½ and 9½ milligrams of oxide of bismuth in 15 grams of liver, salivary gland, kidney and spleen respectively. The urine contained bismuth and frequently albumen and casts. The metal appears to accumulate especially in the spleen, and is eliminated not only through the kidneys and liver, but also through the salivary glands. This latter appears to be the cause of the stomatitis which has been observed as a result of the administration of bismuth.

That severe symptoms of poisoning may result from subcutaneous injection of preparations of bismuth and their application to open wounds, while this is not the case when they are taken internally, the authors think is attributable in part to the fact that oxide of bismuth enters into soluble combinations with albuminous bodies, not only in the presence of alkalis and organic acids, but also in the presence of an excess of albumen; in part to the fact that absorption is continuous.

COPPER.

G. H. Roger³ has experimented with albuminate of copper, and finds that this compound, if injected directly into the circulation, causes death. On the other hand, if taken into the stomach, it is borne very well. The explanation of the latter fact is, apparently, that a great part of the salt is removed by vomiting, then that any portion of the salt remaining in the stomach is converted by the food present, especially sugar, into insoluble and harmless combinations; and if any part happens to be absorbed it does not enter the general circulation, but is retained by the liver, and is afterward separated slowly by the bile. This influence of the liver is shown by the fact that twice as large a dose is needed to kill an animal when

injected into the portal vein, as when injected into the peripheral veins.

Copper causes death by paralyzing the muscles of respiration, the paralysis attacking first the extremities and progressing upwards. The heart beats for a short time after breathing has ceased. Experiments on the muscles of frogs show that copper causes loss of excitability and contractility, but the motor nerves are also affected. Sensibility remains intact, or is weakened only to a slight degree.

NICKEL.

The action of the salts of nickel upon the system has been the subject of a number of investigations, the results of which have been very contradictory. Schulz, Roos and Geerkens administered the acetate of nickel to dogs to the amount of 10-17 grams over periods varying from twenty to thirty-four days without observing more than the slightest alteration in the general condition, with some diminution of the appetite. Others have concluded that the salts of nickel even in small doses — 0.100 to 1 gram — were always fatal. The subject derives its importance from the increasing use of utensils of nickel for pharmaceutical and culinary purposes. In certain countries this metal has been by decree pronounced dangerous, and its employment for these purposes forbidden.

M. A. Riche⁴ has recently investigated this subject anew, and he concludes that nickel may be employed without any danger for holding or preparing articles of food. His conclusion is based upon experiments made on animals, and upon investigations relative to the amounts of nickel which may be dissolved by various liquids (the latter not yet published, we believe). For instance, two guinea-pigs took during ninety-six days 26.3 grams nickel sulphate in quantities gradually increased from 0.025 to 0.250 gram daily without any noticeable effect. A dog during thirty days took with his food salts of nickel corresponding to five grams of the metal with the same result. In a third experiment a dog took during 160 days 100.75 grams nickel sulphate, corresponding to 21.25 grams of the metal, in doses varying from 0.500 gram to 2 grams daily. As long as the quantity did not exceed 0.5 gram daily no effect was noticed. If the daily dose was raised to 0.75 gram vomiting occurred after a few days, and there was a tendency to diarrhoea. The daily dose was raised to one gram during fourteen days, then to one and one-half grams during twelve days, and finally to two grams. Increased vomiting, diarrhoea and general weakness were the results of these large amounts, and after taking two grams for two days the animal refused to eat. After a rest of three days, however, the dog recovered, and the treatment was continued. On the last thirty-seven days of the experiment the amount taken was 0.500 gram daily. At the close of the experiment the animal was in good health, and had increased in weight. In no case was any pathological appearance found in any of the organs. Nickel was found in all the organs, and in the urine, blood and bones in amounts varying from 0.001 to 0.008 gram; the largest amount in the liver and nervous tissue. In the course of the experiments the faeces and urine were frequently examined, and nickel was always detected. It is apparently eliminated through these channels.

In conjunction with Laborde,⁵ M. Riche has further

⁵ Ibid., 1888, No. 2, p. 69, and No. 3, p. 97.

investigated the action of large doses of the salts of nickel injected into the veins, and administered by way of the stomach. They find that, when introduced into the stomachs of dogs and rabbits, they cause in doses of 0.5-3 grams vomiting and diarrhea, followed by lowering of temperature, general weakness, and stupor, but never death.

The action of the salts of nickel is, according to the authors, similar to that of the salts of copper, so far as relates to the essential symptoms, but it is much weaker. The quantity necessary to produce death is larger than could possibly be introduced into food by contact of the latter with the metal.

In acute, as in chronic poisoning, the metal is found especially in the liver and nervous tissue.

BARIUM.

G. Linossier⁶ has made a series of experiments relative to the localization of barium after chronic poisoning with a barium salt. The salt employed was the carbonate, and the poisoning was prolonged for a period of thirty days. He finds on analysis that all organs contain some barium, but that it is present in very variable proportions. The lungs, muscles, and particularly the heart, yield only traces, the liver rather more, kidneys, brain, and spinal cord still more, and lastly, the bones, a considerable quantity, as much as 0.56 in 1,000 parts of bone ash.

PTOMAINES AS SOURCES OF ERROR IN TOXICOLOGICAL INVESTIGATIONS.

Brouardel, Ogier, and Minović⁷ have sought to determine if reactions exist by which ptomaines can be distinguished from the vegetable alkaloids. Their experiments were made upon the livers and kidneys of bodies which had been buried for periods varying from two or three days to two years and longer. They are quite sure that certain color-reactions are characteristic of the vegetable alkaloids. Ferric chloride and alcoholic potash (after previous action of nitric acid) never gave distinct reactions with ptomaines; but it must be admitted that decisive tests for distinguishing alkaloids and ptomaines are not yet given, and that the presence of ptomaines may mask the distinctness of the reactions for alkaloids.

COLCHICINE.

Dr. N. Obolonki⁸ has made a series of experiments for the purpose of determining: (1) The minimum quantity of colchicine which can be detected in mixtures with various organic substances, or in the organs of animals poisoned with the alkaloid. (2) The length of time colchicine resists decomposition under such conditions. (3) What change, if any, it undergoes during the process of extraction. (4) Its most characteristic reactions.

Thirty experiments were made: (1) with aqueous solutions of colchicine; (2) with mixtures of colchicine with various tissues; (3) with the organs of rabbits and dogs killed with colchicine, and examined after periods varying from three and a half hours to four and a half months.

The original paper is referred to for the details of the method of analysis, which is described in full. The alkoid was finally extracted by means of chloro-

form. According to the author, the alkaloid undergoes no change under the influence of chloroform, even if in contact with it for two days. In this statement he contradicts Vaupian and Schützenberger, who state that colchicine, when extracted with chloroform, undergoes a change, after which it is not colored violet with nitric acid.

In experiments with urine, distinct reactions were obtained from mixtures containing 0.05 to 0.005 gram colchicine to 300 cc. urine, even after standing twenty-four hours. When 0.005 gram colchicine was mixed with 500 grams of tissue, positive results were obtained only in cases in which the analysis was made early. If the tissues were allowed to stand for a month at 20° C., the results with such minute amounts were doubtful; that is, they were hardly sufficient in a case involving a charge for murder to establish the fact of poisoning; still they were sufficiently pronounced, in the author's opinion, to show that in spite of the small quantity of alkaloid used, and the high grade of putrefaction of the organs with which it was mixed, the alkaloid was in great part still undecomposed.

Animals poisoned with colchicine died in 10-15 hours after the administration, and the organs were examined either immediately after death, or after periods ranging from twenty-four hours to four and a half months. The amounts of the alkaloid employed were 0.5, 0.1, 0.02, and 0.01 gram. In all cases the intestinal discharges were bloody. In the case of the dogs, vomiting was a constant symptom. Death was preceded by great prostration, and in a majority of cases by violent convulsions. The presence of the colchicine was always demonstrated in all the organs.

The author therefore concludes that quantities of colchicine as small as 0.005 gram can be detected with certainty; that colchicine is a very stable alkaloid, decomposed only with difficulty, and only when the organic matter with which it is mixed is in an advanced stage of putrefaction. In medico-legal cases the most distinct reactions are obtained from the kidneys and urine. The author further concludes, as a result of a number of experiments, that it is doubtful if there is any danger of mistaking ptomaines for colchicine. The best reagent for the detection of colchicine is nitric acid, either alone or with the subsequent addition of potassic hydrate. Erdmann's reagent (nitric and sulphuric acids) is not always satisfactory, but may be depended upon if supplemented by the addition of an alkali. Mandelin's reagent (ammonium vanadate, dissolved in sulphuric acid) is less satisfactory. The preliminary green color passes over into the brown so quickly that it may easily escape notice.

POISONING BY MUSSELS.

M. Dutertre⁹ concludes that poisoning by these shell-fish is due to the presence of numerous bases analogous to the alkaloids, among which *mytilotoxine*, which acts in a manner similar to curare, and produces the paralytic form of poisoning, has been separated. The principles causing urticaria, salivation and gastro-enteritis have not yet been determined. These toxic principles have their seat solely in the liver, but do not appear to belong there normally, but to be the result of some lesion or functional trouble in this organ. In certain persons, however, comestible mus-

sels, which are not poisonons, may cause symptoms of poisoning, usually not severe, simply as a result of digestive disturbances.

VOLATILE BASES IN EXPIRED AIR.

MM. Brown-Séquard and d'Arsonval¹⁰ have demonstrated that the lungs of man, the dog and the rabbit produce normally an extremely active poison, which is eliminated continually with the expired air. Their investigations comprised the study of the effects produced upon rabbits by injecting into an artery or a vein water containing the poisonous principle produced by the pulmonary mucous membrane. The solution of the poisonous principle was obtained (1) by injecting into the lungs of a rabbit or a dog a quantity of perfectly pure water, and afterwards withdrawing the unabsorbed portion; (2) by condensing the vapors contained in the air expired by man or dogs. The symptoms produced by solutions obtained in different ways were always the same. Presumably, therefore, the same poison was injected in each case. The poisonous principle is apparently an alkaloid, for the reaction of the fluid containing the poison was always alkaline. The poison was not destroyed by boiling, and the symptoms produced are always the same, by whatever channel the fluid is injected. The authors consider it very probable that it is this principle which renders confined air so dangerous. The paper of Brown-Séquard and d'Arsonval has called forth a preliminary communication from M. Robert Wurtz,¹¹ who has succeeded in isolating bases, both fixed and volatile, which exist normally in the blood. He is now engaged in investigating the method of elimination. Although his studies are not yet completed, they have already lead him to the conclusion that certain bases are eliminated by the lungs. Among these ammonia seems to predominate, but there is, in addition, an organic base whose reactions are described in M. Wurtz's communication. The author has not, however, obtained a sufficient quantity of this material to enable him to determine its composition or to study its physiological effects.

ETHEREAL SULPHATES IN MORBID URINES.

G. Hoppe-Seyler¹² publishes a series of tables showing the amounts of sulphuric acid in the form of sulphates, and that in the form of ethereal sulphates, and the ratio of the former to the latter, in the urine of patients suffering from various diseases. The results obtained are thus summarized: Deficient or increased absorption of the normal products of digestion, as in *ileus*, peritonitis, tubercular diseases of the intestines, etc., leads to an increase of ethereal sulphates in the urine, as a result of absorption from the intestine of the substances formed by the putrefaction of the normal products of digestion. In typhoid fever there is no such increase. Simple constipation also causes no increase. Diseases of the stomach, even those in which the food lies in the stomach a long time, and then undergoes fermentation changes, never lead to increase of the ethereal sulphates. Putrefactive changes outside the alimentary canal result in an increase; and the result is proportioned to the severity of the putrefaction. The amount of ethereal sulphates may, however, be unchanged, if, at the same time,

other products of putrefaction are increased. This relation exists between indoxyl and scatoyl. In peritonitis indoxyl predominates over scatoyl, the reverse being the case in normal human urine.

The author gives in this paper a resumé of the literature relating to the ethereal sulphates.

PETTENKOFER'S REACTION FOR BILIARY ACIDS.

According to Mylius¹³ the coloration produced in Pettenkofer's test, for the bile acids depends upon the furfural, which is formed by the action of sulphuric acid upon the sugar. Mylius mentions a number of other substances which possess, with cholic acid, the property of producing a red color in the presence of furfural and sulphuric acid.

NYLANDER'S TEST FOR SUGAR.

C. Le Nobel¹⁴ finds this test convenient and certain, if employed warm. He agrees with Nylander that normal urine, if boiled with the reagent, never gives an immediate black precipitate. Such a precipitate occurs only when the mixture is allowed to stand twenty-four hours after boiling. In the absence of sugar a black precipitate is observed in the presence of albumen and peptone, also after the administration of kairin, tincture of eucalyptus, oil of turpentine, and large doses of quinine.

AN UNUSUAL URINARY SEDIMENT.

Thormählen¹⁵ observed the following peculiar urinary sediment in a case of albuminuria. The urine had the appearance of a thick, grayish-yellow mortar-like pap, containing also isolated large clumps, which adhered to the sides of the vessel. The filtered pap, suspended in cold water, was completely dissolved on the addition of a few drops of potassic hydrate and heating. The solution did not become cloudy on cooling, but gave with acids, in the cold as well as upon heating, a thick precipitate. The precipitate produced by nitric acid was not dissolved by heat, but was colored yellow, and upon addition of an alkali, orange red. The solution was precipitated in the cold by sodic chloride, potassic ferrocyanide and acetic acid; and upon boiling, by sodic sulphate and acetic acid; and responded to the ordinary reactions for albumen. Thormählen considers the sediment a peculiar albuminous body, separated spontaneously from a strongly acid urine containing much salicylic acid, not coagulable by heat, but easily precipitated from both hot and cold solutions by acids.

Clinical Memorandum.

CYSTOCELE OBSTRUCTING LABOR; DELIVERY BY VERSION.

BY J. N. HALL, M.D. (HARV.), STERLING, COLORADO.

The interest in this case lies chiefly in the fact that the woman was allowed to become exhausted before help was called for, and hence the child was delivered artfully.

Mrs. L., thirty-eight years of age, eleventh pregnancy, labor pains since waters broke, about forty-eight hours ago. Ten hours before seen she called a midwife. The latter, finding something which prevented progress, summoned aid. When seen by me, 10 A. M., October 23d, pains were severe, but accomplishing nothing; head presenting, O. R. A.; marked caput succedaneum; bladder prolapsed in front of the head; pelvis the largest I had ever seen.

An elastic catheter was passed with difficulty, and three ounces of urine removed. From the swollen condition of the parts and the exhaustion, it was thought that delivery would not occur without assistance. Under ether, the head was held well down from the abdomen, but was still so movable that the forceps were abandoned, chiefly from fear of bruising the swollen soft parts. Hence the child was delivered by version with great ease. Weight, about nine pounds. The caput succedaneum extended from one parietal eminence to the other, and was two inches antero-posteriorly.

The convalescence was uninterrupted.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR OBSTETRICS.

GEORGE HAVEN, M.D., SECRETARY.

REGULAR meeting, Wednesday, December 28, 1887, at 19 Boylston Place.

Meeting called to order by the Secretary, at 8 o'clock. DR. JOHN W. FARLOW was elected Chairman for the following year.

The first business in order was a discussion on THE TREATMENT OF OCCIPITO-POSTERIOR POSITIONS.

The discussion was opened by DR. C. M. GREEN, who said: In speaking of the treatment of posterior positions, I shall allude to the etiology only in so far as may be necessary to explain the treatment that seems to me best in the different phases of the condition; and I shall consider the subject in two divisions, the first embracing those cases where the head is at or above the superior strait, and the second, those where the head has already entered the cavity of the pelvis, as the treatment would differ decidedly under those two conditions.

First, in regard to those cases where the head is at the superior strait or above it. I would say by way of preface that throughout what I shall say I shall regard the pelvis as a normal one. Regarding the fetal head I shall speak as I go along, as the cases would differ somewhat with the size of the head. With the head at the superior strait, and in a posterior

position, difficulty is very apt to arise from the head not perfectly engaging. And that is a very interesting point, as to why it does not engage properly. With the head lying in a posterior position the biparietal diameter has got to pass through the chord which subtends what might be called the sacro-iliac arch on that side of the pelvis towards which the occiput is directed; that is to say, a line running from the promontory of the sacrum to the middle of the ilio-pectineal line on that side. This chord does not equal in its measurement that of either of the oblique diameters. It will be remembered that where the head is attempting to pass the pelvis in an anterior position, the biparietal diameter is going to pass through one of the oblique diameters. For instance, in the O. L. A. position, the biparietal diameter is going to pass through the left oblique diameter of the pelvis and in the O. R. A. position the biparietal diameter is to pass through the right oblique diameter, and that it can do readily under normal circumstances. But when the head is attempting to pass in a posterior position, this same biparietal diameter has got to pass through the chord which subtends the sacro-iliac arch on one side, and that does not measure so much. In the great majority of cases the head is not so large but that this diameter of the head can pass through the arch. Still, in a great many cases where the child is well developed, this diameter is just enough too large to prevent its passing easily.

Well, then, the moment there is any resistance whatever to the easy passage of this diameter, the most natural thing to occur is that the head should become slightly extended, or rather, we might perhaps put it in this way, that good flexion does not take place, since a greater resistance is brought to bear on the occipital arm of the cephalic lever. Then when we are called to the case, the head being, as I have said, above the superior strait, we find the occipito-frontal diameter occupying the brim instead of the suboccipito-bregmatic. Now, of course it is impossible for that diameter to pass, and the clinical history in this case is that the woman's labor goes on, the pains are good, bad, or indifferent, the os dilates in part, but does not go on to complete dilatation because the head does not press far enough down, the woman becomes exhausted, and the condition found is, as I have said, no progress, because an improper diameter is trying to pass through the strait.

In that condition of affairs the treatment is obvious, and the ready reply would be to overcome the difficulties in the case, to promote the flexion which has not taken place, to correct the slight extension which has taken place, and let everything go on. The difficulty is that probably the head was in a fair degree of flexion originally, and yet it did not pass. If even we succeed in flexing the head, the woman may have become by that time so tired out that no longer are the pains sufficient to force the head into the pelvis; so that in reference to the advisability of flexing the head and seeing what will happen when that is done, although I do not say that it is of no use whatever to do it, still I have never seen it do much good, owing to the fact that before that is done usually the labor has been so long in progress that the force of the uterine contractions is no longer powerful enough to do the work it would have done if the head had entered properly in the beginning.

The picture is not one which I will attempt to draw

clinically; but I will speak of the best treatment under the circumstances. That sort of a case is not infrequently seen; and there are degrees in which this condition of affairs may occur, from the slight extension, or non-flexion, of the first part of labor, which any obstetrician should detect, to cases that have gone on even longer, where, instead of slight loss of flexion, there becomes a decided extension, so that the brow of the child dips down lower and lower, and the attendant perhaps flatters himself that the case is progressing, when really extension has gone on more and more, a larger and larger caput succedaneum is formed, and progress has been made to the bad instead of in the right direction.

My own belief is that in that sort of a case the treatment should be something like this: If the case is seen early, if it is found out, as it should have been, that the patient has an occipito-posterior position, it is desirable that the child should be made to rotate so as to occupy an anterior position before the labor has advanced so far that the woman has become exhausted and more serious operative interference must be entertained. I think that may often be brought about by postural treatment. For instance, in the case that we are considering the head is above the strait, and the brow may have entered the strait. The occiput is above the strait, and is riding on the edge of the ilio-pectineal line. If it is in a right posterior position, and the woman is made to lie upon her right side, or in the right latero-prone position, in a great many cases, if the pains are fairly good, as they naturally would be if this process is undertaken early in labor, the head will slide around, and come into the position of right anterior instead of posterior. I have seen that illustrated very prettily quite a number of times, and it is the best course to pursue if the case is seen early and the head is not very decidedly extended or the brow well down in the pelvis. The head having thus rotated into the anterior position, the labor will probably progress normally, or if not, forceps may be readily applied to the anterior head, and delivery accomplished with considerable ease.

It should be said, too, that this rotation of the head forward when it is above the superior strait, can be materially aided by external assistance through the abdominal wall. The body of the child can be grasped, or the hands can be pressed down behind it and the trunk thus assisted to rotate forward, as the head travels around the ilio-pectineal line on the right side. I am not sure about the advantage of having the patient get up and walk about, for I have never tried it. There is no objection to her doing so, for the os would not be dilated at this stage, and of course with the woman erect gravity would help this condition of affairs. I have no doubt that it might succeed when the woman keeping the latero-prone position might not suffice.

Now suppose for any reason this is not to be accomplished, manipulation through the abdominal wall does not succeed, and the head remains in its position. I am not one who believes in using forceps in that sort of a case. I believe that more fetal life is lost with the forceps treatment in that position than we realize. I think, therefore, that if this change of position cannot be accomplished, it is better in the interest of the child to do podalic version and deliver the after-coming head in the manner usually practised. It is surprising, I think, to see for the first time a version

done where the labor has gone on for some time and where, in place of a slight loss of flexion, there is a great extension, so that we are practically dealing with a brow, and at the same time with a head so elongated that the large diameter is above the superior strait. It would not be believed that podalic version could be done in such a case. I believe that even when the brow has almost begun to bulge the perineum a version can be done. My treatment therefore for the head with the large diameters above the superior strait would be the attempt to produce an anterior rotation by means of postural treatment and assistance through the abdominal wall, and failing in that, to employ version. I would say, however, that there are cases where forceps can be safely used, and I have used forceps myself in that condition of affairs, after flexing the head and judging that it was not a large child and that the head ought to pass. That, however, I believe to be an exceptional method of procedure. I believe that as a rule version is a safer thing for the child, and it ought to be safer for the mother when we remember how dangerous high forceps are for the mother. So much for those cases where the large diameter is not engaged in the superior strait.

Now then, passing on to the second class of cases, where the head has entered the pelvis, and where the occiput is posterior, we come to those cases which have escaped the first peril of non-engagement, or non-engagement in a suitable diameter, where the head has passed successfully through the superior strait, and entered the cavity of the pelvis. Of course many of these cases go on without difficulty, anterior rotation takes place, and the child is born. And I have no doubt that it is sometimes not appreciated that the child lay in a posterior position. It is so easy in the absence of a proper external examination not to make a diagnosis.

But unfortunately a great many of these cases do not proceed to normal delivery. The patient's pains may be pretty good, but the anterior rotation does not take place; flexion is lost, gradually the larger fontanelle comes down lower than the small fontanelle, and the attendant is surprised to find at one examination that where he had previously felt a small fontanelle he no longer feels it, but does feel a large fontanelle. Extension has taken place, and he now has a case which, unless properly treated, will not go on to normal delivery. Of course, occasionally in these cases flexion will take place, but that would be the exception.

Now there are three factors which are necessary to the anterior rotation of the head when it is in the pelvic cavity. First, the pains should be sufficiently strong, the child's head should be perfectly flexed, and the soft parts should be sufficiently firm. We must have good pains, a good, firm perineum, and good flexion. Now then, the treatment of any case would consist in promoting, as far as one can, these conditions. If the pains are not good, of course we may not be able to help it. But we ought not to have let them become poor, as is too often the case. The woman should not be allowed to go on in fruitless labor until the uterus is tired. But granting that no other reason exists, and that the pains are not strong enough from general weakness, or from any cause whatsoever, then of course as we cannot supply the *vim a tergo* (though quinine is said sometimes to do

it), we must put in force the *vim a fronte*; namely, the forceps.

Then in regard to the question of flexion. I have never seen a case that I could not flex; although of course they do occur, it has never been my fortune to meet one. It is not always easy, by any means, although it may be possible. In a great many cases flexing is easy by simply exerting counter-resistance against the forehead,—simply holding two fingers against the forehead during several pains, and if the pains are good they will, by forcing the occiput down, cause flexion. If there are no pains, then we must substitute counter-pressure for counter-resistance, and with firm pressure we may be able to restore flexion. That failing, we may go to the other end of the lever and see what we can do with the occiput. We may pass up one hand, and with that succeed in flexing the head. If that fails we have still the use of the forceps-blade or vectis, which is the same thing, and with that means pull down the occiput. Of course if it can be done with the hand it is better, on the principle that it is always better to use the fingers rather than an instrument. That failing, there still remains the method of flexing the head with the forceps reversed, which was brought to the attention of the Massachusetts Medical Society by Professor Richardson two years ago in a paper on this subject. That is a method which it is comparatively easy to employ, and which certainly works very well. It is a very pretty mechanism, and it increases also our respect for the forceps, as increasing their power. Of course it simply means this: In all cases where we use the forceps we turn the forceps-tips to what we might call the leading point. The leading point of the O. L. A. position, for instance, is the occiput, and the tips of the forceps go towards the occiput. In the occipito-posterior positions we want the occiput to be the leading point. If we have marked extension the brow is the leading point, but we don't wish to deliver by the brow; so that it might be stated in this way, that the forceps would be so introduced that the tips would point to what we wish to be the leading point. When we introduce the forceps with the curve reversed we accomplish this thing. Then usually by exerting a fairly moderate traction, the head will flex.

Then we have to go back to our three factors, and as we have seen, the powers of the uterus, if not sufficient, must be supplemented in some way. The condition of the parts is an important thing. If the floor of the pelvis is not sufficiently resistant to give that resultant which is needed to throw the occiput forward, of course that forward rotation will not take place, consequently there is no need to dwell on the fact that firm parts are necessary. They may or may not be present. In any event, if they are not present, and if the pains are not very strong, we certainly shall not get anterior rotation. In many cases there is no loss of flexion. I don't mean to imply that that is a necessary accompaniment of posterior positions. The flexion may be perfect. In one case that I remember the flexion was perfect and had been so all through. In fact the head had been in the pelvis for ten days, and as the patient was a primipara the soft parts were firm; but the *vis a tergo* was vastly inadequate, and instrumental assistance was absolutely necessary.

What are we to do with any occipito-posterior position where flexion either has not been lost, or if lost

has been reproduced so that we have simply our well-flexed head and no progress? That would mean in most cases insufficient pains, and to come to the aid of the uterus forceps must be applied. Now if forceps are put on in the usual way with the tips anterior they are not acting in the way that they do in all other cases. That is to say, they are not put on with the tips pointing to the leading point. With the occiput posterior, and the ordinary curved forceps, the Braun or the Simpson, the forceps-tips point toward the anterior part of the head, and if forceps are so introduced we certainly don't get rotation forward (unless, as occasionally happens, the head rotates within the blades), and we do deliver that head with the occiput posterior, and take the consequences almost invariably of a serious perineal tear; so that it is a matter to be thought of very seriously that if by any means we can produce rotation forward it is our duty to do so. And it seems to me that it can be done.

I wrote a paper not long since, and it was criticised by one who did not read it, I am sorry to say, and lest I might be misunderstood again, I will explain myself here in detail. In that paper I spoke of the fact that I had repeatedly put on curved forceps to the extended head with occiput posterior, flexed the head and then proceeded to deliver with the forceps still reversed. Now I don't recommend that procedure at all. I think it is an extremely hazardous one. I have been very fortunate that I have done no damage. It can be done, however, and the only question is, is it the best thing to do? I say decidedly not, because we have in the straight forceps a much better instrument, and one which can be used without any risk of damage in reasonably careful hands. The straight forceps are not easily bought, however, those that are found in the shops being simply handle and blade without shank, and too short for use except when the head is on the perineum. Now with straight forceps applied, at the same time that traction is made, a slight amount of force may be used to rotate the head. It is of course definitely understood that I would not under any circumstances exert any rotation force whatever except during traction. I believe that if that rotating power is applied only with traction, it can do no harm and is successful. It has been so in my hands, and I think it would be so in the hands of any obstetrician. It requires no especial skill, and is simple; and we avoid all risk whatsoever to the soft parts.

If, however, one attempts to deliver with the tips of the curved forceps reversed, then he must remember that the tips are liable to plow into the vaginal wall and do serious harm; so that if curved forceps are used the operator ought to remember where the tips are, and not simply know where the handles are. He draws solely with reference to these tips, keeping them in the mind's eye, and keeping the tips in the axis of the vagina constantly. In that way delivery can be effected without harm. I have done it seven or eight times. I only mention that so that a man without straight forceps might hesitate before he puts on curved forceps in the usual way. I have a great horror of leaving a patient with a serious tear of the perineum, and I myself don't enjoy sewing up such a tear. The doctor is tired, the patient is tired, and it is no reason why a man should follow a line of treatment with a great risk of damage because he says: "I can sew it up afterward." If he has a serious tear he

may not get a primary union. The patient may have to have several operations afterwards before her soft parts are restored. It is too serious a question with her to make any operation a light one. But it is comparatively seldom that a large head can be delivered with the occiput posterior, as it certainly would be in most cases if the curved forceps are applied in the usual way with the tips anterior, without causing such a tear: so that I would be understood to-night as favoring very much the use of straight forceps in these cases, and of only employing the curved forceps in case the straight forceps are not obtainable. And I also believe that in careful hands curved forceps may be used with the tips reversed, with less risk to the soft parts than in delivering the head with the occiput remaining posterior. I say this with some hesitation, but if it leads to a discussion which is useful, I shall not regret it. I would not teach that to students; speaking to physicians it is different. It is not a thing to teach, but I simply express my own private view when I say that I should much rather myself do that than apply the forceps in the usual way knowing that that would mean delivery with the occiput posterior.

I believe statistics prove that only four per cent. of occiput-posterior positions are delivered as such. All the other ninety-six per cent. rotate, or can be made to rotate. It would seem to me that that per cent. could be reduced. I don't believe that even four per cent. of the occiput-posterior positions need be delivered as such. I have seen but two cases delivered with the occiput-posterior. Every other case has rotated either itself or by assistance. One of the cases was a difficult forceps case and a very large child; and that will lead me to speak in a moment of the influence a large head may have on the mechanism. The other was a case where the child came out in one pain after I reached the house. It was a little child, and might have been born in any position. We may say, I think, that even so small a per cent. as four can be reduced, and that we may have practically all the occiput-posterior positions born as anterior, with a due regard to the essential conditions of anterior rotation.

One word more about the reversed application of curved forceps and the delivery with them reversed. I don't mean that the head is delivered with the forceps reversed, at that time. I mean that the blades are reversed when applied, are turned in the vagina, so that the head is born as if originally in an anterior position. To repeat once more, I don't want to be understood as recommending that procedure. It is simply a choice of evils. If I would not do version, and had not straight forceps, and could not get them, I would sooner put curved forceps on in this way and deliver, than to put them on in the ordinary way and deliver with the occiput remaining posterior.

One word more. What often makes a great difficulty is the very large head. When it is very large it seems as if the mere size of the head made it impossible to rotate. Of course there is a limit to nature's capabilities, as we all know, and with the very large head I suppose that with the increased powers necessary to do the rotating that the rotating does not take place; but I have seen only one case where that rotation was not accomplished, or could not be accomplished. That case was delivered as a posterior variety.

I presume there are points which I have forgotten,

as I neglected to make any notes, and if I have done so I have no doubt that Dr. Reynolds will think of them and bring them up.

DR. EDWARD REYNOLDS said: I think Dr. Green has covered almost everything, but there are a few points which I have noted down. First, in the matter of treatment of these cases it seems to me that we must emphasize the importance of early diagnosis. We cannot treat the position without knowing what the position is, and we all know that there are very many of these cases in which early diagnosis by vaginal examination is a very difficult matter. It is in just these cases that we can appreciate most fully the value of abdominal palpation. If a man is in the habit of palpating every case, and making his provisional diagnosis before vaginal examination, I think he relies almost as much upon the former as upon the latter, and that gives him a means of knowing at the very beginning, in the greater number of cases, that he has an occipito-posterior position. Now he is prepared to watch the labor, and if the ordinary vaginal examination is inclusive he will not hesitate to make it more thorough, under other, if necessary.

I think if this course was pursued in every case we should have a much smaller proportion of cases in which a posterior position has gone on to extension, emptying of the liquor amnii, and all the difficulties that follow. I think it is almost impossible to deal with the treatment of these positions intelligently without considering the possibility of the occurrence of contracted pelvis. We know that in the flattened pelvis the head very frequently enters transversely, a position which is easily mistaken for the posterior occiput; and that in a contracted pelvis there is normally some little extension as it comes through the brim. I should, therefore, on being called to a case where I found the head resting upon the brim with a slight extension, feel obliged to measure the pelvis carefully before operating.

If the pelvis is found flattened, with the occiput posterior or transverse, of course, taking all things together, there would be little to think of except version, forceps to the flattened pelvis being much less efficient. If, on the other hand, the pelvis is found to be lessened in the transverse diameter, version becomes a much more serious matter. And if the pelvis is decidedly justo minor, I should myself feel inclined to attempt flexion and manual rotation to the front, followed by the application of forceps, in spite of the fact that any disturbance of the relation of the fœtus to the mother may complicate version, if done afterward.

Dr. Green will recall a case which we saw together a year or more ago, in which a firmly contracted ring around the neck of the child forced us to abandon version, and in which we did flex the head manually, and rotated to the front with ease, and finally, after a great deal of difficulty, delivered with forceps. We were both struck by the fact that one arm of the child had been swept round behind the back in such a position that, had we afterwards done version, we should probably have had an arm jammed under the occiput, and lost the child in consequence. I think it is well worth remembering that it is a dangerous thing to rotate a child that you may wish to turn afterward.

As to what Dr. Green has said about the extreme lowness of the brow in which version is still possible, I have been struck with that in one or two cases. I

think that this is true, not only in presentations of the brow, but also in certain cases in which labor has been going on for a long time, with the head arrested at the superior strait, and in which the first thing felt is the head, low down. I think if you have a patient under ether it is very easy to detect these cases by passing the finger up behind the head, and I have found in cases in which I supposed that it was in the inferior strait, that the parietal boss was really above the promontory. I think it is worth remembering that especially in brow cases you ought to get a finger way round behind and feel for the promontory before deciding that the head is low, the molding may be so excessive.

In speaking of cases in which the head has entered the pelvis, I think we should divide them into two classes, which, of course, merge into each other, but which would make a great difference with me as to what the treatment might be. There are a good many cases where a small head has extended for want of resistance from the soft parts, and is jammed by the occipito-mental diameter across the inferior strait. These cases can be handled in almost any way. The forehead can be pushed up, or the occiput can be pulled down with the fingers or with the vectis, and I have seen one case in which rotation could be effected with the hand. This with a little ether. In a case a little more difficult than that it is extremely easy, after flexing the head with the fingers, to apply the forceps, not exactly to the side of the head, but so that the posterior blade impinges lightly upon the side of the occiput, and the anterior blade upon the diagonally opposite side of the forehead, and the mere pressure of the forceps in locking them would start rotation, and traction, with a little rotary force, would complete it. In such cases I think there is no difficulty whatsoever in rotating with curved forceps.

If, however, you are dealing with a case in which to the difficulty of extension is added the difficulty of tight adaptation between the head and pelvis, it seems to me that we must be more cautious as to what we do with any instruments. The fingers will probably fail to produce flexion, and the vectis will not only fail, but may do harm from the greatly curved blade getting into the sub-occipital tissues, or from the leverage which the single blade has upon the soft parts of the mother, and we should probably have recourse to reversed forceps. With, however, tight adaptation, and the consequent necessity of making powerful tractions in order to deliver, it seems to me that in rotating with curved forceps we are running great risks of doing harm to the vagina, simply from the fact that the attempt to put on powerful traction makes it difficult to guide the points of the forceps, and remember just where they are. That, of course, is a case where the possession of the straight forceps is a great advantage.

As regards the possibility of rotating in all or nearly all cases, though my experience has been small, I have certainly seen two cases in which, after every attempt at rotation, the occiput persistently swung back into the hollow of the sacrum. It seemed to me directly posterior. One in particular started as an O. D. P., and as soon as flexion was effected, which was done by means of pressure upon the forehead, the occiput, instead of rotating forward, passed directly back. There it stayed, in spite of any attempt to rotate it forward. It seems to me that such cases must

be delivered face to pubes. What the cause was, I was unable to determine. There was nothing abnormal about the pelvis, so far as I could see.

There is, I think, another class of cases in which extension is very likely to occur, that in which the fetal head is somewhat abnormal in shape. I remember one case which I have delivered twice, in which each child's occiput seemed to be very long. Both were anterior positions, and yet both showed all through labor a marked tendency to extension, no doubt from the over-long occiput, and it seems to me that when such cases do take the posterior position, they are certainly the cases in which traction upon the occiput is likely to be most efficient; exactly the cases where, with the fingers or vectis over the occiput, we are likely to succeed without further efforts.

DR. JOHN P. REYNOLDS said: I would say briefly that the remarks made by Dr. Green on high forceps express my own judgment. I think that the personal equation counts for something; that with the same case one man will prefer version, and do it with great ease, while his neighbor, with more facility in the use of the forceps, is tempted to try that instrument. I think the general conclusion is what Dr. Green has stated: "I always like to recur to that elementary fact in regard to diagnosis, that the presence of two fontanelles fairly within reach should settle the probability that the unaided natural forces will bring the posterior fontanelle forward without difficulty, provided always that we are dealing with a pelvis and a cranium of average relative proportion, and I think it is quite important, in discussing the matter generally, to lay stress upon that fact.

I don't like the term "posterior position." The posterior variety of the left or right position seems to be a better use of terms, and this way of speaking carries with it the fact that it is the position on the left or the right side of the pelvis which varies the mechanism, not the condition that the occiput looks toward the posterior quarter, or the anterior.

If any gentleman has had the curiosity to read what has been said by the advocates of the vectis, I should be very glad to know whether my own understanding with reference to the advocacy of the vectis in medical writings is correct. I have not had access to the original works, which are mainly those of Belgian authors, but my impression has always been that the use of one blade of the forceps in the manner described to-night is not what the friends of the vectis would consider its proper use. I suppose that the vectis is always meant to be used from the front of the pelvis, either on the parietal bone or the mastoid process, the pressure being made from above downward; while the other hand of the accoucher, bearing upon the handle, protects the mother's soft parts. I think that when a man passes up his hand in front and pushes one blade of a forceps behind, he is not performing an operation proper to the vectis. It is, I suspect, such an employment of the vectis that its partisans intend, when they picture the instantaneous and perfect relief that they give after long, violent, and useless efforts with the forceps. In one word, they flex the head, or they fully extend the head. I may be entirely wrong. The vectis was, however, mentioned, and I venture to make this criticism.

I question whether there may not be some gentleman here, who, from having no special interest in the subject, fails quite to grasp what Dr. Green so perti-

nently said in regard to the guiding end of the cranium. In reading a book as familiar as Cazeaux, among general rules for applying forceps, one, for instance, that the man attempting it should be sure that there is nothing in between his blades except the child; and another, that he should never use force, etc., it will be found formally laid down that this, the concave edge of the blade, should always be turned toward that end of the cranium that we wish to bring round to the pubes. That covers all that has been said to-night about the posterior application of the forceps. Let the given cranium be transverse in the pelvis, and low enough down not to come into the category of strictly high forceps cases. Of course, one blade will here go in over the posterior ear, and the other lie behind the pubes. We wish to have the occiput come round; therefore, according to the rule just mentioned, we should put the concave side of the blades toward the occipital end of the cranium: the purpose being only to flex the head, not at all first to rotate. This whole matter of "posterior application" may be found stated at length in Cazeaux. Any operator of fair experience in the use of the forceps may without extreme risk afterward rotate without removing the instrument. That point has been treated very clearly to-night, but I like to connect this reversed application of the forceps with the author, whom I have named.

Just one other matter of nomenclature: the speaking of anterior rotation and posterior rotation. From the shape of the pelvic cavity, all rotation is rotation forward, and we cannot too well bear in mind the excellent description of Uvelak West, that there are two ways in which the cranium comes down: One, the good, in which the back end of the cranium is lower, descends, and rotates to the front; the other, perverse, in which the front end of the cranium gets lower, and rotates to the front. There is no such thing as posterior rotation. We must fix our attention, as Dr. Green urges, upon the leading part, the part that is on the way to the front of the pelvis. If the undesirable front part of the head rotate forward, the desirable posterior part has no chance but to remain behind. It can no longer "rotate" anywhere.

Dr. O. W. DOE said: There is only one point in the remarks of Dr. Green that I will touch upon, and that is the point of assisting rotation before the head becomes engaged in the largest diameter. He spoke about taking the lateral position. It occurred to me whether that might not be supplemented by the patient's taking either the knee-elbow position or by lying on her back, with the hips elevated during the interval between the pains. I think that in this way, with pressure by the fingers in the vagina, you might make the head rotate more easily in the superior strait. Another point, about the descent in cases where it is impossible to rotate the head: I should think that the per cent. of cases that do not rotate would be less than four. In my own practice, I have met with but one case of occiput posterior where I was unable to rotate the head, and I have certainly had more than twenty-five cases which rectified themselves. There was just this one case that I could not rectify.

Dr. FARLOW: How was that case delivered?

Dr. DOE: By forceps, with the occiput posterior, and without rupture.

Dr. E. W. CUSHING: I would like to ask of those gentlemen who have tried it whether, in putting on

the forceps with the tips reversed, it is handier to get at it with the woman on the side or with her on the back, as I should imagine it would be necessary to keep the handles pretty well back in delivering in that way. I have never had occasion to try it. It seems to me, in regard to rectifying the position in the beginning, that a distinction must be made between those cases that call in the attendant after the labor has been going on, and those where he is called in the beginning, as in private practice. If there by palpation of the abdomen, he could discover that it was a posterior position: it seems to me that it ought not to be very difficult to get the child turned over. I think many of us will remember the way, in the courses in Vienna, in which they turned the child over and then back in the abdomen, to demonstrate it to the students.

I don't think Dr. Green mentioned what he would do in those severe cases where the position becomes still worse, and the face is low down in the pelvis: whether in these cases, under ether, the head can be pushed back.

There is a method which, I think, may be recommended in the beginning of these conditions, where Dr. Green advises version. If you go so far and get the hand into the pelvis, and find the head in this position, and the brow down, the question arises whether, instead of going up and getting a foot, it would not be possible to grasp that head and turn it above the pelvis, aided by such postural change or manipulation of the abdomen as would turn the child within. I do not think that has been referred to.

Dr. J. P. REYNOLDS: In reply to the question asked by Dr. Cushing, the nates should, of course, be brought well up to the edge of the bed; such a posterior application of the forceps can only be well made when the head is tolerably low in the pelvis. This method is not advisable in the high position. I venture to make one other remark that occurred to me as Dr. Green was speaking about the attempt to rectify the variety before the head was fixed. I think it will be found, as a matter of obstetric literature, that authors vary as to what side they would turn the child for that purpose.

In the case supposed, I should have turned the woman to the right rather than to the left, not agreeing with the speaker. At any rate it is curious what a divergence of opinion there is. The child holds a certain definite relation to the central axis of the body, the head will not shoot itself fairly, so to speak, into the barrel of the pelvis, and by making the weight of the body fall over towards the mother's right, some accoucheurs expect better chance of having the good end of the cranium drop into the inlet.

Dr. GREEN: I would like to say, while it is fresh in my mind, that I did place that woman on the right side, and not on the left. This matter of postural treatment is one of great interest, and in reference to what Dr. Doe said, I didn't mention the knee-chest position, but it would seem that the man's ingenuity at the time would adopt the position to bring about the desired result. Of course, with the patient in the knee-chest position, or standing up, or supposing the patient should walk around for a time, if the os was not in such a state that there was risk of rupture of the membranes, I think when we remember the inclination of the pelvis it would seem very likely that the person's sitting up or walking about would bring about the change.

As to the matter of grasping the head with the hand, as Dr. Cushing has said, there is only the one objection, that we run a risk of so disarranging the parts that we may get into trouble, as in the case that Dr. Edward Reynolds referred to. So with such a position of the head we try all the different ways, the idea being to get, if possible, the child back to the front. In some of these ways I believe the head can be swung round in a great many cases. If the labor has gone on for some time the brow may be so deep that postural treatment may be entirely useless, and we may have to turn with the hand after we have disengaged the head.

The importance which Dr. Edward Reynolds put upon the early diagnosis is a matter which cannot be insisted on too much. It is of course important in every branch of medicine. If this is bad, we need not get the bad results which follow the occiput-posterior position, because with the head high it is not a bad position, and I think can generally be easily rotated without any operative interference, so that too much importance cannot be laid upon this matter of early diagnosis. The diagnosis by external palpation is also very important. The importance of it has been so dwelt upon that students are now taught to make their diagnosis first by palpation, and they are taught, in making the report of a case to say: Provisional diagnosis, so and so; and then to proceed to give the results of the vaginal examination, and state whether the diagnosis is confirmed or not. At any rate the importance of abdominal palpation is much better appreciated now than formerly. If this is practised in a great many cases the diagnosis would be sure. If that is not conclusive, if one has a shadow of a doubt of the provisional diagnosis, and he does not confirm it easily, I think it is a matter of great importance to make the diagnosis early in labor with the patient etherized. It is best to etherize the patient to do it, and then it is a simple matter. It has seemed to me that men sometimes make mistakes because they do not push their diagnostic powers far enough. I say that knowing that I have made that mistake myself. We are too apt to put up one finger or two fingers and not finding anything, to say: "Well, I guess it is so." We ought to be ready to swear to it. Why not use the half-hand, or the whole hand, if necessary. If there is such a caput succedaneum that the sutures and fontanelles are obscured, so that we cannot feel sure, etherize the patient, and put in the hand under careful antiseptic precautions. Feel the whole head; at any rate be absolutely sure. What Dr. Edward Reynolds said was very much to the point.

Dr. CUSHING: I would like to know if examinations during the last weeks of pregnancy are not important.

Dr. GREEN: They are important, but one must remember that positions change, although of course they may not. If one can make an examination, and find that the head is in the pelvis, he knows that the pelvis is not contracted; and he knows that if the head is in the pelvis, the position is not going to change.

I was also glad to hear Professor Reynolds make the point that there was no such thing as posterior rotation. That is a point for us all to remember. The thing to think of is that the leading point of that particular case is going to rotate to the front and of course the other end must rotate backward. If it is a face where the chin comes forward, then it is the

back of the head that must go backward. What takes place when the occiput goes backward is that the brow rotates forward and becomes the leading point. It is not the occiput that rotates backward forcing the brow to the front; it is the opposite.

Dr. CUSHING spoke of further extending the head in brow presentations and converting them into face cases. I thought that was outside our discussion to-night. It is a point always to be remembered, however, if we have the occiput posterior, and cannot get the anterior rotation, and cannot overcome in any way the tendency to anterior rotation of the brow, it is better to make that a face than to deliver it as a brow with forceps put on in the usual way. With the occiput right posterior, the child's head when extended would become chin left anterior, and that would be a very favorable position for delivery. And if that extension has taken place, the forceps delivery in the usual way would be a simple thing comparatively. The only thing would be the risk to the child, whether as much as from other operative procedures, I will not say.

One thing more in regard to the posture of the patient in applying the forceps. I have always done it with the woman on the back. When the forceps are applied reversed, as I have said, one is all the time thinking of the tips. His mental eye is fixed upon the tips of the forceps, which are to be kept in the lumen of the vagina. If one goes on pulling, keeping his eyes on the handles, he will make sad havoc with the vaginal wall. With the straight forceps that danger disappears. Then a man sees what way he is pulling, from the handles. Thus straight forceps are the safest instrument, and should be used if obtainable.

THE NEW YORK ACADEMY OF MEDICINE.

STATED MEETING March 15, 1888.

Dr. FREDERICK R. STURGIS read a paper on

SOME QUESTIONS IN CONNECTION WITH SYPHILIS
HEREDITARIA TARDA.

The subject, he said, was one of much interest to the general practitioner, as well as to the syphilographer, on account of its relations to the etiology of many cases met with. In certain instances the agency of syphilis was suspected, without the physician's being able to prove the actual presence of this disease. It was only very recently that the manifestations of late hereditary syphilis had been at all appreciated by the profession. During the last twenty years much had been accomplished in clearing the matter up; but notwithstanding all the advances that had been made in this direction, many points still remain unelucidated. The question was still asked, Can hereditary syphilis remain latent for years? Until recently, this was supposed to be a fact in certain exceptional cases of acquired syphilis; but the weight of evidence now showed beyond question that such a thing never occurred in the latter. It was the generally accepted opinion at the present day in cases apparently of this kind that other and minor manifestations of syphilis invariably preceded the so-called tertiary symptoms. There was always an initial lesion, although no trace of it might afterwards be found.

It was at one time supposed that in all cases of hereditary syphilis the disease showed itself at birth,

but the fact was now recognized that many cases occurred in which the children were apparently perfectly healthy when born. Statistics showed, however, that in a large proportion of cases syphilitic lesions made their appearance before the end of the third month. Of 249 cases collected by Diday and other authorities, the disease showed itself in 118 by the end of the first month, in 117 between this time and the end of the third month, and in 14 later than the third month. Of Diday's own cases, in two the lesions did not appear until after the first year. In instances in which the disease just showed itself at a very late period the question of acquired syphilis always had to be taken into consideration.

The usual history of inherited syphilis, exclusive of those cases in which the child was born syphilitic, was, that after a few weeks or months the earlier manifestations of the disease made their appearance, such as a macular eruption, or mucous patches of the mouth and tongue. At this early stage there was usually no eye or ear disease, or affections of the bones or joints. These lesions soon passed away, and there might be no further syphilitic trouble for years, or until the age of puberty was reached, when there might develop keratitis, otitis, disease of the bones or joints, or deep ulcerations in the buccal or nasal cavities. Unless the early history of the patient could be accurately learned, it might be supposed that these late manifestations constituted the first appearance of the disease. Thus, Fourrier related a case in which a man of thirty, who strongly denied having ever had syphilis, became affected with gumulous ulcerations of the penis. By communicating with the patient's family physician, however, he ascertained the fact that his mother when *enroute* with him had acquired syphilis from her husband, that at the age of two years he had had syphilitic disease of the knee-joint and peripheral ulcerations, and that when an infant he had infected the nurse who suckled him with syphilis; while at the age of fourteen he had keratitis. The missing links in the history were thus furnished by the family physician.

Dr. Sturgis said, in conclusion, that even the diagnostic sign of Hutchinson's teeth was often absent in these cases, but he believed that in every instance of hereditary syphilis, if the history could be fully ascertained, it would be proved that these later lesions had always been preceded by earlier and lighter manifestations of the disease.

DISCUSSION.

DR. EDWARD L. KEYES said that he could state with positiveness that it had not been his experience to see any instances of what could be called late hereditary syphilis. He had met with alleged cases of this character, but in all of them he was able to detect some scar or deformity which convinced him that the late lesions present were not the first manifestations of syphilis in the patient. He had followed up a number of individuals who were known to have had hereditary syphilis, and found that after various periods of latency the disease sometimes broke out again before the age of twenty-one. Before they reached the age of twenty-five, however, when crystallization of the system had taken place, the trouble had been pretty well gotten through with; and he did not recall a single instance in which a new symptom of hereditary syphilis had appeared after this latter age.

Still it was quite possible for us to believe almost anything in regard to syphilis, because it was such an irregular and erratic affection.

The character of the disease in any particular case was also largely a matter of soil; so that he did not believe in a virulent or a benign type of syphilis *per se*. The seriousness of the symptoms would depend to a great extent on the constitutional characteristics of the subject, and in this connection he referred to three brothers, all of whom had syphilis at different times, and in all of whom it produced grave lesions of the central nervous system, which in one of them proved fatal. Yet the third of the brothers gave the disease to a young woman, who had it in an extremely light form. The younger the subject, as a rule, the more serious the disease was apt to be, whether it was hereditary or acquired, on account of the more active changes taking place in the system during early life. Hence, the older the subject the less serious its effects; and in the aged these were comparatively trifling.

He then related the case of an infant born under his observation, in whom the disease was so markedly developed that he despaired of its life. It shed its nails, and had pemphigus of the soles and palms, bad snuffles, and enlarged epiphyseal extremities. He commenced treating it, however, with one-fiftieth of a grain of bichloride of mercury every two hours, night and day, and it soon began improving. At the age of six months it was not only alive, but thriving vigorously, and it still continued to take the same dose of the bichloride every four hours. In future years, if this child should have syphilitic lesions, this early history might be lost sight of, and it might perhaps be considered an instance of late hereditary syphilis. It was easy to see how, in many instances, the early manifestations of the disease might entirely escape observation or be lost sight of. The method of treatment adopted in this case was one which, he said, he had worked out some years ago at the New York Foundling Asylum, and he had always found it very satisfactory. It was his usual practice to give the one-hundredth of a grain of the bichloride every hour, if this was practicable, and he had found that this never produced mercurialization or diarrhoea. In fact, at the Foundling Asylum it had often seemed to have a salutary effect upon the diarrhoea from which the infants were so apt to suffer.

DR. P. A. MORROW said that the subject under discussion had been comparatively neglected, and that it was only within the last few years that we had begun to appreciate how wide might be the impress of syphilis upon the organism. In many cases it was impossible to get at the history of the individual from birth, and he said he should be very much inclined to doubt whether any patient whatever who manifested the later lesions of syphilis had entirely escaped the earlier symptoms of the disease. Only to-day, however, he had examined a girl of eighteen, whose reputation was above suspicion, who was undoubtedly suffering from hereditary syphilis; yet it was impossible in this instance to get any history of syphilis in infancy. She was the subject of many cicatrices, while the soft palate and palatine structures, as well as other portions of the vocal apparatus, had been swept away, and she was completely aphonic.

He went on to say that he could see no reason why hereditary syphilis should not continue throughout a

lifetime, just as the acquired disease was often known to do. It was essentially the same affection. So far as his experience went, there was absolutely no history of the early manifestations of the disease in many cases; but this was, of course, merely negative evidence, and it was contrary to his general knowledge of the course of syphilis to suppose that in any instance the patient had really escaped these earlier manifestations. In conclusion, he referred to an infant affected in much the same way as that mentioned by Dr. Keyes. It was apparently moribund, and it was a wonder that it lived at all. It did live, however, and several weeks later developed into a healthy child; yet in this instance no medication whatever was employed. He did not wish to depreciate the value of mercury in such cases, but here the mother only was treated.

DR. ROBERT W. TAYLOR said that it was his firm conviction that there were always some manifestations in early infancy, though these might be so ephemeral and unaccompanied by destructive action, that they left no permanent trace. We might expect the later lesions to appear at almost any time up to about the twenty-first year. In the chapter on inherited syphilis in Bamstead and Taylor's work, he said that he had placed the usual limit at twelve years (although, as was well known, manifestations of hereditary syphilis occasionally showed themselves at a considerably later period), for the reason that he feared that other affections might be confounded with inherited syphilis, which was so comparatively rare at these later ages. Dr. Taylor said that in his work published in 1876, he was the first American to call attention to the bone lesions of syphilis, and to bring them out of the slough of so-called scrofula. All the way up to the age of puberty we might expect the later manifestations, but when we got beyond the twenty-first year it was pretty hard to say whether you were dealing with hereditary syphilis or not. As a rule, the activity of the lesions occurred before the tenth or twelfth year. He could not agree with Dr. Keyes in regard to the comparative lightness of syphilis in old people, for in his experience he had found it exceedingly severe and troublesome in such subjects.

DR. L. BOLTON BAXGS said that he was in accord with the other speakers in regard to the question at issue. His own observation had been that almost invariably, by careful inquiry and investigation, he was able to find some history of previous symptoms; and he mentioned a case of late tubercular syphilide of the face in a patient twenty years of age, in which he found that there had been unmistakable signs of syphilis in early childhood.

DR. CHAPIN mentioned the case of a child of four years, in which syphilitic periostitis affecting both tibiae appeared, apparently without any previous manifestations of the disease, as the patient had been carefully watched from birth by its parents. He agreed with Dr. Keyes as to the importance of the kind of soil into which the syphilitic infection was introduced, and said that he had known of many syphilitic infants with snuffles and mucous patches who were fat and robust, and really seemed to thrive on the disease. As to the later lesions occurring in individuals beyond the age of ten or twelve years, he thought they might as well be called scrofula as syphilis. If there were no typical lesions of syphilis present, it was his practice to put the patient on cod-liver oil and other tonic

treatment, as he was unable to tell whether the trouble was really syphilitic or not.

DR. ALEXANDER S. HUNTER related the case of a young woman of eighteen who suffered from extensive destruction of the nasal bones and soft palate, which he believed to be due to hereditary syphilis. He had had the opportunity, however, of interrogating those who had been with the patient from infancy, and they stated positively that there had been no manifestations of the disease until she was fifteen. Still it was, of course, entirely possible that they might be mistaken on this point.

DR. L. EMMETT HOLT related cases in his experience, and said that he thought it was the easiest thing in the world for the earlier manifestations of hereditary syphilis to be overlooked. He then called attention to the importance, as a diagnostic sign of the disease, of enlargement of the epitrochlear glands. Although this condition might be due to other causes, in his experience very few cases of syphilis occurred without the enlargement of these glands.

The President, DR. A. JACOBI, said that when syphilis occurred at birth it was not always easy to recognize positively. There was sometimes great difficulty in distinguishing between a syphilitic and a rachitic bone, or rather cartilage, and particularly when the ribs were affected. If the difficulty, then, was great at this early period, it was still greater later on. It was a fact that where a number of children were born in a syphilitic family the manifestations were apt to become less and less marked in each successive child, and the disease might at last be undistinguishable from the symptoms of so-called rachitis or so-called scrofula. In regard to the age at which hereditary syphilis first made its appearance, it was a peculiar fact that the cases first occurring in adolescents or adults were all reported by the older writers of twenty-five, thirty, or forty years ago. It did not appear that any of the later writers mentioned any such cases. Thus, Burke said that he never saw one, and Diday, who said the same thing thirty years ago, was still of the opinion that such cases did not occur. Having referred to other authorities, Dr. Jacobi said that probably one reason why the earlier manifestations were apt to be overlooked in former years, was on account of the universal use of calomel, which was an anti-syphilitic remedy, in all the diseases of children. Personally, he said, he had seen a few cases of late hereditary syphilis. The oldest of these patients was over thirteen when the late lesions presented themselves; but in this instance it was easy to trace the disease back to infancy.

DR. STURGIS said that he had for the most part reserved an expression of his own opinion until the close of the discussion. What he meant by the late lesions of hereditary syphilis was those occurring after the age of five years, and he believed that such late manifestations did not occur without previous symptoms. He mentioned the case of a patient of seventeen, who was sent to him for diagnosis, with a cold inflammation of the knee-joint, which had resisted all forms of treatment. On careful examination he was able to detect traces of an old keratitis and otitis. The children in whom these late lesions were found were apt to be born apparently healthy, and when the earlier manifestations did occur they might escape notice and remain untreated. It was in the untreated cases that

the late lesions were most liable to make their appearance. At the age of five or six years we were likely to have punctate interstitial keratitis, and disease of the ears, joints, etc., and nothing would be found to do any good until the iodide of potassium was resorted to. Under this treatment the child would probably get well rapidly. At ten there was apt to be another outbreak of the disease, and about the age of puberty the most serious explosion usually occurred. After the age of twenty-five the disease would generally be found to be acquired. If a patient over this age presented himself with the earlier symptoms of syphilis we could almost invariably suspect that the disease was acquired, since the early manifestations of the inherited disease were most likely to show themselves within three months from birth, and always did so within twelve months.

Recent Literature.

A Manual of Physiology: A Text-Book for Students of Medicine. By GERALD F. YEO, M.D., Dabl., F.R.C.S. Third American from the second English edition. Philadelphia: P. Blakiston, Son & Co. 1888. pp. 758, and 319 illustrations and a glossary.

This is a new edition of a book already favorably mentioned in this JOURNAL. The most noticeable improvement will be found in the chapter on the functions of the brain. The illustrations have become slightly more numerous, and are much better printed in the copy before us. The glossary has also grown in extent and quality. On the whole, it is still a good book of medium size, whose teaching is generally sound and conservative. The present condition of our knowledge of deglutition is, however, not given, and the relation of urea to the liver is not presented with that exactness which various trustworthy experiments would seem to warrant. The description of the "chyme" on page 159 is at variance with that of the glossary.

Miner's New Index Rerum for Students and Professional Men for Saving Knowledge. Pocket size. Also arranged for An Account Book for Petty Accounts for Physicians and Others. JOEL A. MINER, Ann Arbor, Michigan.

Of these indexes, several sizes are published, one or other of which will be found useful by physicians, lawyers, and other students. Topics beginning with A are placed together in the first section of the book; those with B in the second section, and so on. Each section is shown to the eye after the manner of an index, so that the book can be opened at each section instantly. There are two possible ways of subdividing the topics that come under each letter: One is the strict dictionary arrangement of topics, which subdivides the pages under each alphabetical section by the letter that first follows the initial letter. The second method groups the topics under each letter into six groups, according to the first following vowel (a, e, i, o, u, y). This second method is followed in these indexes.

— Governor Hill sent to the Senate, last week, the name of Dr. E. C. W. O'Brien, of Buffalo, to be Health Officer of the port of New York.

THE BOSTON Medical and Surgical Journal.

THURSDAY, APRIL 19, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLFS AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

CEREBRAL LOCALIZATION.¹

In spite of the attacks made upon it by Brown-Séquard and Goltz, the doctrine of the localization of function in the cerebrum since the day when Broca showed that the left third frontal convolution contained a centre for speech, has steadily gained ground, notwithstanding the seeming contradictions of experimentation and of clinical and post-mortem observations, and notwithstanding the contentions of its adherents on questions of detail.

In the first place the doctrine of localization finds a certain amount of support in the results of anatomical investigation. It is not entirely without significance that in the so-called motor regions of the cortex, there are ganglion cells of a different shape from those in other parts of the brain. The great amount of work that has been done in the study of secondary degeneration, von Gudden's researches into the degeneration of the optic tract, and Flechsig's investigations into the development of various systems of fibres, all tend to the belief that there are definite tracts in the brain, whose function it is to conduct special forms of nerve force.

Physiological experiment, added to the hints afforded by anatomy, certainly lends confirmation to this belief. Of course there are abundant sources of error. It is not easy to say whether the symptoms that follow the removal of a part of the brain are symptoms of arrest or symptoms of deficit, and, when the only final test in regard to this point is applied—that of time—another source of error arises. In all animals, it is possible that there may be a certain amount of substitution in the brain; when one centre is destroyed its functions may be performed wholly or in part by some other centre. The lower down in the animal scale we go the more pronounced this substitution is, and experiment has shown that permanent loss of function is far less common from the destruction of given centres in the guinea-pig or rabbit than in the dog. Even in man, however, this substitution does occur in childhood; as in the cases where, after destruction of the

¹ Continued from page 382.

left third frontal and upper temporal convolutions in infancy, the child has learned to talk, and, when it reached adult life, it has become aphasic from lesion in the same region in the right hemisphere. Nevertheless, experiments on animals have shown, and continue to show, that after removal of certain portions of the cortex, there are permanent symptoms of deficit. Take, for instance, the experiments made to determine the visual centre, which Brown-Séquard thinks does not exist. Goltz, rejecting the theories of cluster-localization, showed two dogs at Baden-Baden in 1886, from which he had removed both occipital lobes, yet the animals could see. Such an experiment, therefore, would seem to disprove the theory of Munk that the occipital lobes contain the centres for vision, and that removal of both lobes will produce blindness. Goltz's methods, however, are not accurate. He has himself abandoned his earlier method of washing away the brain-tissue by a stream of water, as it has been proven that this method cannot be depended upon to remove definite portions of brain-tissue. Moreover, it was shown by Fritsch, at the Congress of Internal Medicine at Berlin, in 1884, that Goltz, even with his present methods, is not accurate in his "symmetrical" extirpations of portions of the cortex, and that his attempts at extirpation had not removed the regions which he claimed had been extirpated, for instance, that the entire region of both posterior extremities and part of the centre for one anterior extremity were intact when he claimed he had removed them. The difficulty of removing both occipital lobes, is, in fact, so great, that Munk, who attempted to remove them in eighty-five dogs, succeeded in doing it completely and satisfactorily, and in keeping the animals alive in only four. The arguments against Munk's theories in regard to the centres of vision, therefore, cannot be accepted until Munk's experiments have been repeated, and until it has been shown that removal of the centres in the occipital lobes has been complete and that the animals have still been able to see, which has not yet been done.

The symptoms seen after the removal of portions of the brain are in many cases permanent, and are symptoms of deficit, rather than of arrest. Even if we assumed that the lesion caused symptoms of arrest solely, it is hard to see why a lesion in one place would cause arrest of one function, and in another place arrest of another function, unless there is some localization of function in those regions, if a lesion anywhere can cause inhibition of any function, still accurate observations are wanting to show, that lesion of the occipital lobes can cause monoplegia, or lesion of the ascending convolutions can cause blindness.

The weight of clinical evidence also seems to confirm the results of physiological experimentation. Many cases that have been reported are, of course, defective. The observation and the analysis of symptoms has not always been complete, and the observers have not always been competent. Post-mortem investigations, too, have been misleading from the defective knowl-

edge of the anatomy of the brain. Nevertheless, the clinical evidence in favor of localization is too great to be set aside. Wilbrand's and Seguin's researches into the question of hemianopsia, for instance, have confirmed Munk's discoveries; and now that it is known that there are centres in different parts of the brain for each of the different functions of speech and not one common centre, the case, where there has been a lesion in one of these recognized centres and no speech-disturbance have become much fewer and the majority of them are too inaccurate to establish a theory.

The theory of exactly limited centres, the sharply-defined circles depicted by Ferrier, is probably not correct, nor is it certain that the psycho-motor centres are purely motor; in fact, it is more probable that the psycho-motor centres are, as Munk thinks, rather sensori-motor than purely motor. These centres, as Luciani and Seppilli think, and as Horsley's observations seem to prove, probably overlap one another, and shade into one another, but that there are more or less distinctly localized centres for various functions in the cortex seems fairly well proven at the present day, and Brown-Séquard's views, instead of being novel, are, in spite of the weight of his name, merely a repetition of the theories of twenty years ago, theories which are now abandoned by most physiologists.

MASTOID INFLAMMATION.

THE public and the profession have heard so much of this subject of late, in connection with the finally fatal attack from which a widely known public man has been suffering, in New York, and for which the usual operation was performed—an attack said to have originated from exposure during the late blizzard—that a short review of the salient points in connection with mastoid inflammation, may prove of interest to our readers.

The history of the recognition and treatment of diseases of the mastoid process is a curious and interesting one. It shows the gradual evolution of what are now well-known pathological processes and generally acknowledged surgical procedures from the age of total ignorance, though temporary, because misunderstood, success, through obliquely equally temporary from misunderstood failure, till finally modern pathology has placed the diseases of this region and their treatment on a firm and scientific basis.

In the older writers, occasional mention is made of the possibility of operations in this region for the relief of certain aural symptoms. Riolaenus, in the latter part of the fifteenth century, proposed opening the mastoid cells; and in Sir Thomas Brown's letters to his son, dated about 1650, he seriously discusses, but advises against "opening of the mastoides to afford exit to the tumultuous noises and winds therein confined." Petit is generally considered to have been the first to perform the operation of opening the cells for the removal of secretion, about 1750, but Jasser

was the first to do it for caries of the bone in 1776. Occasional operations, generally futile, followed for the relief of subjective noises and other aural symptoms, till Bergen, a Danish surgeon, had it performed on himself to relieve an obstinate deafness, with violent tinnitus, the result of which was his death from meningitis. From this time the operation fell into disrepute, and can only be said to have been fully re-established within the last twenty-seven years (since Troeltsch's case in 1861), when modern pathological research has shown the different conditions which exist within the bone, together with the complications resulting from this disease of the bone, and modern surgery has demonstrated the methods of dealing with these conditions and complications.

The mastoid cells form part of the tympanum, their diseases are secondary to diseases of that cavity, and are essentially various forms of otitis and periostitis. Imagine a bone like other bones, with its periosteum, minute vessels penetrating its substance, and the other characteristics of osseous structure, but, unlike other bones, hollow and lined internally with a mucous membrane, which forms an internal periosteum. Put such a bone within the skull, next the brain, let the dura mater act as periosteum on two of its surfaces, connect the venous circulation of its mucous membrane directly with the sinuses of the dura mater, and we have the chief peculiarities of the mastoid process, except that it should be remembered that its cortex is very thin.

Pathology shows that in almost all cases of tympanitic suppuration, the mucous membrane of the mastoid is also more or less inflamed, in fact, that there is a periostitis within the bone. We have here a simple explanation of almost the whole pathology of mastoid disease. As the result of this internal periostitis we may get suppuration confined within the bone, a round-celled infiltration of the substance of the bone, a breaking-down of this cellular infiltration with resulting caries or an organization of this infiltration with resulting hyperostosis, an extension of the suppuration along some of the minute foramina to the external surface of the bone, setting up external periostitis, which, if it occurs within the cranium, means inflammation of the dura mater, or finally we may get an extension of the inflammation along the bloodvessels to the brain sinuses, giving phlebitis, thrombosis, and embolism.

The infrequency of severe mastoid disease compared to the frequency of slight inflammation of this part (as has been said, almost every case of tympanitic suppuration showing some involvement of the mastoid), we can refer only to the *vis medicatrix nature* which resolves the inflammation before it has proceeded much beyond the stage of congestion. In severe cases of the disease we may get any or several of the results of otitis, limited to a small portion of the bone or involving the entire mastoid and petrous or even the whole temporal bone, and, with an extension of the disease inwards, the complications of meningitis,

phlebitis of the brain-sinuses and brain-abscess. The frequency of tympanic suppuration can be appreciated when it is remembered that probably nine-tenths of the suppurations of the ear (otorrhœas) are due to inflammations within the tympanum and the so-called "gathering in the ear," is now known to be a disease not only liable to injure or destroy the hearing, but subject to very dangerous complications both in the brain and in the deep tissues of the neck.

PRODROMIC SIGNS OF LOCOMOTOR ATAXIA.

At a recent meeting of the Société de Biologie, Paris, Galezowski, in speaking of the precursory signs of locomotor ataxia, mentioned two to which his attention had been particularly attracted of late years: paralysis of the muscle of accommodation, and anæsthesia of the peri-orbital region. These, he thinks, are often the first symptoms of the disease in question. The paralysis of accommodation is not accompanied by mydriasis or paralysis of any other of the muscles innervated by the third pair; as this paralysis is always limited to one eye, it gives rise to no trouble of vision when the patient uses both eyes.

The paralysis of accommodation which succeeds diphtheria is always binocular, while that which results from certain contusions of the eye is not accompanied with anæsthesia of the orbital region. The same is the case with the paralysis which follows syphilis.

In hysteria, according to M. Galezowski, the paralysis of the ciliary muscle is always accompanied with mydriasis, and in general paralysis of the insane, besides paralysis of the accommodation, there is hemianopsia.

TREATMENT OF EPITHELIOMA BY MILD CAUSTICS.

In the *Journal of Cutaneous and Genito-Urinary Diseases* for January, 1888, Dr. Daniel Lewis has an article on the treatment of epithelioma by mild caustics, which he condemns as stimulating, rather than repressing these growths. One patient was treated for epithelioma of the lip by nitrate of silver; as a result, the cancer spread until it involved the left side of the face and the inferior maxillary region, and the patient died.

Another case was that of an old lady who had an epithelioma of the ala nasi on the right side, which was removed by curetting, and on the left cheek a smaller one, to which pyrogallie acid ointment (one part to two) was applied. The disease on the right side got well, but that on the left continued, and after months of trial surgical interference was resorted to, and a prompt cure effected.

He thinks that pyrogallol may be successfully used in semi-malignant ulcers of the skin which have no indurated borders, but that it is very injurious in epitheliomata.

Upon a healthy skin, cauterants merely destroy the surface epithelium, while stimulating the deeper tissues into greater activity, and, if there is a diseased area, this must also be excited. "This brings us," he says, "to the laying down of this proposition, justified by experience, as well as philosophy: *No mild caustic application should ever be made to any cancerous surface under any circumstances.* Only such caustics are admissible as completely destroy the diseased tissue; such remedies destroy the vessels and lymphatics adjoining, and so prevent dissemination of cancer elements."

TWO NEW TEREBINTHINATES.

PROSSER JAMES, in the *Lancet*, March 10, 1888, calls attention to two new products allied to the terebinthines: the essential oil of mountain pine and hydrate of terpin.

The former is obtained from the *Pinus pumilio* (mountain pine) by distillation with water. A crude preparation of the mountain pine is used much at the German spas to impregnate the water of baths in the treatment of rheumatism and gout, and also by inhalation in bronchial affections. The purest preparation is known as "pumiline." It has the odor of fir balsam, is thought to be disinfectant, and is less irritating than other fir oils. The oil may be inhaled in a steam atomizer, ten to twenty drops at a time being mixed with the boiling water, or it may be diffused through water by means of magnesia or talc in the following proportions: forty to sixty minims of the oil, a scruple of magnesia, and one fluid ounce of water. It can be taken internally like terebine, and its effect on the organs is much the same.

Terpin hydrate affords a curious contrast to the other preparation. It has little taste, no odor, is solid and crystallizable, and insoluble in cold water. It is given in pills of two grains each every three or four hours, or in wafer paper, or the hydrate may be dissolved in glycerine and given in the dose of two or three grains to the teaspoonful as a beginning dose. As a tasteless, odorless substitute for the terebinthines, whose general properties it possesses, it is principally employed.

MEDICAL NOTES.

—Of the two latest deaths from rabies among patients who had submitted to Pasteur's treatment in Paris, one was a boy, aged four, who was bitten by a mad dog on December 6th last, and was under treatment at Pasteur's Institute from the 12th of December, 1887, until the 7th of January, this year. He died of hydrophobia on January 22d. The second case was that of a woman, aged fifty-two. She was bitten on January 23d of the present year, and was placed under Pasteur's treatment on January 29th. She died on February 17th, of hydrophobia.

—Dr. Morell McKenzie has received a decoration from the Emperor Frederick.

—The danger of too violent exertion for elderly persons especially those with cardiac weakness are familiar enough in general to medical men, but they are not sufficiently appreciated by the laity. According to the press reports Mr. Matthew Arnold's lamented death seems to have been caused by such imprudence. He arrived in Liverpool last Saturday to meet his daughter who was on her way to England from New York. During the evening he was in exuberant spirits. He took a long walk and tried to clear a railing near the house by a jump. He failed but again made the attempt, taking a running jump, and succeeded. No ill results appeared at the moment. Mr. Arnold knew he suffered from a disease of the heart, and Dr. Sir Andrew Clark had warned him against any sudden exertion. The next day after this exertion he went to church, apparently well, and after luncheon went out to walk with Mrs. Arnold. He was still in high spirits. Soon after leaving the house he suddenly fell forward and never afterwards spoke. Immediately after Mr. Arnold fell he was carried into the house of a doctor near by. He was still breathing, but was unconscious. The physician poured spirits down his throat, but he never rallied and died within four minutes after being taken indoors.

—Sir Andrew Clark has been elected president of the Royal College of Physicians after quite a sharp contest, his principal rival for the honor being Dr. Richard Quain.

—We are indebted to an esteemed daily contemporary for the following curious account of the surgical interference in Mr. Conkling's case: Dr. Sands made an incision back of the right ear, on what is called "the squamous portion of the temporal bone." After the incision a chisel was inserted, and the back of the skull was raised by the use of a mallet. This is known as the "mastoid" process, as distinguished from trepanning. The aperture thus made permitted about an ounce of pus to ooze out, the pus not being extracted, but simply permitted to flow.

—In introducing the Budget to the British parliament the Chancellor of the Exchequer announces a tax of £1 on "pleasure horses." Our English medical brethren evidently fear that this is to be construed to apply to doctors' horses, though it is difficult to see why it should. If the English doctor has to pay a tax on both his horse and carriage he will, in many cases, have to go afoot. The plan to tax "all horses which could be broadly described as belonging to the well-to-do" would certainly often exempt the doctors, while the difficulty on the more tenable basis of taxation in discriminating between horses owned for pleasure and use is well-nigh insuperable.

—The fashionable obstetric nurse is telling her lady patrons that her dates are all full up to a year in advance. The ladies desirous to stand next in her list will have to be endowed with an unusual amount of prescience.

— A book agent presented himself at the New York Polyclinic, when he was found to be affected with small-pox. He confessed that during the ten days that he had been ill he had continued to ply his craft.

— A correspondent of the *Lancet* describes the case of a patient aged about forty, who had been suffering for a week from constipation, with extreme pain and great tenderness and swelling in the region of the cæcum, also vomiting and flatulent distension, which was considered a case of obstruction with accompanying typhilitis. The physician prescribed belladonna, calomel, and opium, and gave copious soap-and-water injection, ordering hot applications to the part, but without much benefit. He afterwards injected warm olive oil, followed by more soap-and-water, with the result, in a few hours, of dislodging a quantity of hardened feces, containing a great number of live white maggots. He asks the question, Were the maggots the result of fecal decomposition? Or were they antecedent to it, and really the cause of obstruction by setting up inflammation?

BOSTON.

— The Massachusetts General Hospital has recently been given \$50,000 by Miss Helen C. Bradlee, of Boston, as a memorial of her brother, the late L. Putnam Bradlee.

— The Executive Committee of the Instructive District Nursing Association writes to inform us that since April 9, 1888, there may be found at No. 6 Carver Street an agent, who, on personal application of the physician, or in response to a note signed by the physician, will provide a nurse for the care of the sick poor, and for the instruction of those in charge. The nurse will be sent to any part of the South End, North End, or West End, or the city proper. The agent will be at the office to receive applications from 9 to 11 o'clock, A. M., every day of the week, Sunday excepted. If the physician wishes to see the nurse, he will find her at the office from 2 to 2.30, P. M. If he be unable to meet the nurse at the office, he is requested invariably to leave *written* orders for her, with address of the patient, with the agent. Every application will receive the immediate reply of the agent by the mail of the same day. Nurses will not attend the patient on Sunday nor in the night.

NEW YORK.

— A special committee of the State Charities Aid Association, appointed in January, 1887, has made a report advising the separation of the administration of charities from that of correction in New York City, the suggestions contained in which are to be embodied in a bill soon to be presented to the Legislature. It is recommended by the Committee that the present Department of Charities and Correction be divided into three parts, each part to be under a separate Commissioner, who shall be responsible to the Mayor. These Commissioners would be as follows: (1) A Commissioner for the sick and infirm, controlling the hospitals and almshouses, containing at present about

3,200 persons. (2) A Commissioner for correction, controlling the city prisons, the penitentiary, and the work-houses, containing now about 4,600 persons. (3) A Commissioner for dependent children, controlling the children's and infants' hospitals and the idiot asylum, containing about 800 persons. The Committee also suggests that the system proposed would be incomplete unless the Commissioner of the third department had some power of supervision and transfer over the 15,000 or 20,000 children now supported by the city in private institutions.

— At the last meeting of the Section on Public Hygiene and State Medicine of the Academy of Medicine, Dr. Henry D. Chapin read a paper on "The Survival of the Unfittest," in which he maintained that the methods of our modern civilization tended to perpetuate unfitness and defective types, such as were represented by criminals, lunatics, and paupers.

— The corner-stone of the Montefiore Home for Chronic Invalids, a Hebrew hospital which is to cost \$175,000, and will be situated on 138th Street, was laid with appropriate ceremonies on the 5th of April.

— The annual dinner of the New York Post-Graduate Medical School and Hospital was held at the Hotel Brunswick on the 10th of April. Dr. D. B. St. John Roosa presided, and in his report the Secretary, Dr. Rice, stated that during the present session there were 265 students in attendance.

Miscellany.

UNPLEASANT LUNG SYMPTOMS FOLLOWING THE USE OF ANTIPIRYNE.

OUR readers have already had their attention called to unfortunate results following the use of antipyrine. The following note, communicated to the *British Medical Journal* by Walter Sturge, M.D., presents further ground for caution in the use of the drug by persons who have never taken it before. The writer says:

"A member of my family liable to migraine was attacked in the ordinary way a few days ago, and I administered for the first time a dose of five grains of antipyrine in powder, with the following curious result: Five minutes after taking it, the 'deadly sickness' which was previously present seemed to give way, and an 'expanding sensation' was felt, rising from the stomach upwards. Almost immediately she sneezed violently for about twenty times running without pause. The face and eyes became deeply suffused; tears began to flow; quantities of mucus flowed from the nose; the breathing became hard and labored, accompanied by a feeling of suffocation; there was complete inability to lie down. A violent cough shortly came on, and large quantities of mucus were expectorated; at the same time, there was very profuse sweating.

"After these phenomena had lasted about half an hour, intense itching was felt on the insides of both thighs, and, on examination, there was found a thick outcrop of urticaria, which soon extended on to the

abdomen. There was also a strong coppery taste in the mouth—not continuing, but coming on in violent bouts—and an equally strong smell of the same metallic nature, also intermittent. There was a loud singing in the ears, which felt intensely congested. The pulse was quick and very full.

“After the symptoms had lasted about three-quarters of an hour from the commencement, they gradually disappeared, some tightness of the chest and running at the nose remaining for four or five hours longer. The sickness accompanying the migraine completely disappeared as soon as the drug had begun to work; the headache also disappeared for a time, but came back slightly about four hours afterwards.”

MR. KNOWSLEY THORNTON ON APOSTOLI'S TREATMENT OF UTERINE FIBROIDS BY ELECTROLYSIS.

MR. THORNTON thus states his views of the electrolytic treatment of fibroids, in the *British Medical Journal*, March 24th.

(1) I think the whole discussion premature, because we know that fibro-myomata are most uncertain in their habits of growth and retrogression when left entirely to themselves, the most surprising alterations taking place in periods of three, six, or twelve months. Such alterations are still more common if the patients are carefully handled as to diet, alcohol, rest at the periods, and special medicines.

(2) Nothing which has yet been published by Apostoli or his followers is inconsistent with these natural, or slightly aided changes, and the results obtained are probably as much due to the rest and care while under treatment, powerfully aided by the effect on the nervous system of confident hope of cure, as to the specific action of electricity.

(3) No results can have any scientific value till the cure is proved by a sufficient interval of health for at least twelve months after the treatment has ceased.

(4) We do not yet fully appreciate the dangers of the method. I know of one case in which rapidly fatal pyæmia followed a very few applications in the hands of one experienced in the use of the method. The journals tell us of narrow escapes, and even such careful manipulators as the Keiths record a serious case of cellulitis, of which the gravity is not lessened by attributing it to the carelessness of the patient.

(5) I would ask the profession not to be carried away by the enthusiasm of any one in a *revival* of this kind, but to wait patiently for definite results, confirmed by sufficiently long intervals.

Let those who believe in the new “panacea” work for a year or two, and then show us their cured patients; that is, if they then have any to show.

A SANATORIUM IN BRAZIL.

A SANATORIUM has been established by English enterprise in the highlands of Brazil, at San Paulo, thirteen hours by rail from Rio de Janeiro, and three hours from Santos. The latter port is twenty-three days' voyage from Southampton, Eng., and twenty-eight days from New York. Great claims are made for the climatic advantages of the town for pulmonary invalids. The atmosphere is dry and exhilarating, and the barometric range so remarkably limited

that it does not exceed three-quarters of an inch throughout the year. The average maximum temperature in the hottest month, January, is 80° in the shade; in the coldest month, July, 72°. The average minimum night temperature in January is 64°; in July, 49°. The number of days on which there is a brilliant sunshine for the whole or the greater part of the day averages 235 per annum, and such days are pretty equally distributed throughout the year. Unlike the Mediterranean winter resorts, San Paulo has no unhealthy season of the year. Invalids are recommended to spend both seasons there, and it is a disputed point which is the more beneficial; but those who like sea-bathing and want a change, can go to Santos for sea-bathing in June or July. Two miles from the city, a sanatorium has recently been built by an English gentleman, on a hill commanding a splendid view. It is well drained, and supplied with excellent water. It has reception rooms, billiard and bath rooms, and every modern convenience; while the town, at present containing a population of 40,000 to 50,000, has the comforts desired by invalids, and is surrounded by a country abounding in pleasant walks and good hunting.

MORE ALLEGED MILK INFECTION THROUGH SCARLATINA.

Our readers are already familiar with the Hendon and other cases in which scarlatina is claimed to have been caused through a milk-supply. The *Lancet* gives the facts concerning the last of these alleged cases as follows:

Mr. Henry Armstrong has prepared a very careful report on an outbreak of scarlatina, in the Jesmond district of Newcastle-on-Tyne, which is apparently associated with the use of milk from a certain dairy. The outbreak was sudden and limited in duration, 19 cases in 16 households occurring between January 27th and February 6th: and of these 19 attacks 17 occurred in persons having their milk from the same dairy. The milk came from Gosforth; but amongst fifty families in that district taking the same supply no cases were heard of; there were also 169 households in Newcastle who had their milk from the same dairy, and who remained unaffected. Suspicion, therefore, seems at first sight to free the dairy itself, and this notwithstanding the fact that some scarlatina appears to have existed in the house of one of the dairy workers some few months before the outbreak. The cows are also declared to have been healthy, one only having had chapped teats; but on this point we can hardly, in the present state of our knowledge, accept any definite assurances. Coming next to the distribution of the milk, there was an incidental purchase of additional supplies in both the Newcastle milk-walks, and although inquiry as to these incidental sources of supply led to no results inculping them, the very occurrence complicates the story materially. However the milk became infected, the infection must have been a limited one both in point of time and in amount. Both milk-walks were attacked, one to the extent of $\frac{5}{8}$ and the other to 9 per cent. of households supplied. But whilst the actual source of infection remains undiscovered, the report forms, by reason of its careful preparation and argumentation, a valuable addition to the subject of disease-distribution through the agency of milk services.

Correspondence.

SIX LIVING GENERATIONS.

GEORGETOWN, MASS., April 11, 1888.

MR. EDITOR, — I think the following family history, which came under my professional notice by my being called to attend the mother of the *sixth living generation*, is without a parallel in the country.

Last May I attended Mrs. Newall Rogers, of Byfield, aged sixteen years, with her first child. I was then informed, and I have since taken pains to verify the statements then made, that this baby is the *sixth living generation*, with ages as follow:-

Great Great Great Grandmother . . .	95 years
Great Great Grandmother . . .	74 "
Great Grandfather . . .	59 " 8 months
Grandfather . . .	39 " 4 "
Mother . . .	16 " 2 "
Child . . .	11 "

All the above are still living to this date.

Can any of your readers instance even five living generations?

Yours truly, R. B. Root, M.D.

JOHNSON'S EDUCATORS AS A DIABETIC FOOD.

40 BOYLSTON ST., BOSTON, April 2, 1888.

MR. EDITOR, — In the *Journal* of March 23d, in an article entitled "The Value of So-Called Diabetic Foods," occurs the following statement, (see section 7): "Dr. Johnson's Educators. These biscuits are recommended very strongly by the seller, who assured me that they were absolutely free from starch." For light on this point let your readers consult my Educator and other circulars.

Also the following with regard to diabetic foods, which is all I have published on this subject, and corresponds with every statement made by us with reference to them:

"To those who are unable to use starch in their food I would call attention to our gluten flour and special diabetic food in the form of bread and crackers both plain and shortened. Not excelled by anything of the kind on the market."

These latter foods, mentioned in sections 8 and 9, page 287, of the *Journal*, by Dr. Harrington's own analysis and estimates contain but 23 per cent. and 30 per cent. respectively of starch, or the equivalent of 25.55 per cent. and 33.33 per cent. of sugar-forming substance, less than any other on the list, by his own showing.

Notwithstanding this I am accused (in section 11, paragraph 4), with dishonesty and fraud, and he commends a Graham wafer of another's make, with its 51.15 per cent. of starch as a superior diabetic food to mine. The above presumes that diabetic foods, and not the educators, were analyzed. The fact that absolute gluten has never been produced except in the laboratory, is quite significant in this connection.

I desire the co-operation of the profession in the work in which I am engaged, and doubt not I shall obtain it when honesty and integrity shall be found united with the requisite ability.

Yours in the interest of true living,
WM. L. JOHNSON.

LETTER FROM BERMUDA.

HAMILTON, BERMUDA, April 5, 1888.

MR. EDITOR, — The copies of the Boston papers which reach us show how fondly winter still lingers with you. We scarcely realize what it means when we read of the thermometer marking 8° (F.) as morning after morning we step on to the veranda to find the mercury at 68° or 70° (F.) Bermuda is a small group of islands scarcely covering nineteen square miles, but this contracted area is crowded with natural beauties. They are situated 677

miles south-east of New York, in latitude 32° 15', about on a line with Charleston, S. C. They are separated from the American coast by the Gulf Stream, on the eastern and southern border of which these islands lie. Bermuda is of coral formation, and is perched on the top of a submerged mountain, associated by some with the lost continent Atlantis. Its vegetation is a strange mixture of the cedar and the palm, but almost any of the tropical plants grow here under cultivation.

The climate is a peculiar combination of semi-tropical heat, tempered by the cool and moist breezes from the sea. It is essentially a marine climate. The thermometer shows a daily average in the past ten years of 71° (F.) with the dew point at 64° (F.). During the period of ten years the records of which I had access to (through the courtesy of Mr. Frith, the librarian of the islands), the highest record found was 90° (F.) and the lowest was 47° (F.). This latter occurring only the 18th of last month (March, 1888) during the blizzard which swept the eastern shore of America. January, February and March are called the winter months, but there is no distinct division of the year into seasons. During these months it rains somewhat more frequently, especially in the day-time, but the rain-fall shows only 1.46 in. more in these than in any other season of months. These daily showers last only ten or fifteen minutes, and are not a hindrance to out-of-door life. Visitors soon accommodate themselves to the English way of always carrying an umbrella.

The average record by months of the temperature, barometer and rainfall is as follows, for the period of ten years. The observations were made at 10 A. M., 12 M., and 3 P. M.

Month.	Thermometer.	Barometer.	Rainfall.
December . . .	67.2	30.075	5.69 in.
January . . .	68.5	30.182	6.46 in.
February . . .	68.3	30.272	6.20 in.
March . . .	68.2	30.075	4.78 in.
April . . .	68.2	30.066	3.97 in.
May . . .	70.0	30.041	5.02 in.

After the middle of March the weather becomes more settled. Days of almost constant sun-shine occur for two and three successive weeks, the showers, if any, usually occurring during the night when the mercury has fallen from 6° to 8° (F.).

The prevailing winds are from the tropics, though during the months of January to May the north-west winds come over the sea from New England, and make us remember that winter is still holding on.

Fires are occasionally needed, but chiefly to counteract the excessive dampness. Heavy flannel will be needed by a person coming as early as April 1st. After that date the season grows warmer.

As a resort for invalids Bermuda has enjoyed considerable reputation. It has very many advantages, and few disadvantages, but at the outset of the trip we encounter its only serious disadvantage. The voyage is sixty hours' sail from New York, but it is said to rival the celebrated English channel for severity. Of one hundred and six passengers on the Orinoco when we came, only twelve were free from the "mal-de-mer."

Once safely landed in Bermuda we find a beauty of air and scene which immediately revives and interests the visitor. For one who simply wishes a place to pass the season and escape the rigors of our northern winter, no place can be pleasanter than Bermuda. Nassau and Cuba fall far short of the attractiveness of these coral islands. Malaria is positively unknown here. All surface water is quickly absorbed by the porous coral formation.

Careful inquiry among intelligent physicians shows that there is no disease to which the islanders or their winter guests are exposed. Cardiac diseases do very well here. The gastric pain and dyspepsia, is relieved, the circulation is improved by the increased work of the sweat-glands, and the tropical sun brings out a good complexion. I have

seen three cases of valvular disease greatly improved by a visit this spring to these islands. Chronic bronchitis and asthma in the same way improve.

Patients with phthisis will probably not improve, unless they are in the very earliest stage, and need the change and rest desirable at such times. There is a large proportion of consumption among the native Bermudians, and many deaths among the visitors who come here hoping to stay their disease. There have been two cases of hæmoptysis under my observation during my six weeks' stay. The symptoms do not ameliorate, and the patients return none the better for the trip. It seems to me a grave mistake to send consumptives to Bermuda.

The climate of Bermuda seems to be well adapted for persons of advanced life. The native Bermudians are noted for their longevity, the record showing that deaths at eighty, and even ninety, are very common. Old people recuperate rapidly, and receive much benefit.

But the greatest class to whom Bermuda offers her healing balm is the worn out and jaded business man; the nervous and debilitated woman, whose unknown diseases have the range of our medical vocabulary from "nervous pros-

tration" to "a complication of diseases." These people find here plenty to do. The driving is the special attraction. Hard, smooth roads, and an attractive point to drive to, make this very popular. The walks are by paths which lead through beautifully laid out grounds, while to him who enjoys the sea there is splendid yachting and excellent fishing.

Bermuda has one more advantage—it is 677 miles away, and has no communication with the world except a weekly mail steamer. No other spot on the face of the footstool is so isolated, unless it be St. Helena. Once here the patient must stay long enough to gain the benefit of time.

To the over-worked and weary who need the three R's, rest, recreation and refreshment, with quiet amusement to keep their minds occupied, who can enjoy the blueness of a coral sea, who can interest themselves in the coral animals and the geology of coral reefs, and so enjoy a change of air and scene without becoming the idlers of a summer's isle, unless they prefer it, to such as these I would say that Bermuda offers splendid chances, and if any one chooses to take them I think he will be repaid.

Very truly, JOHN B. BRAINERD, M.D.

The meteorological record for the week ending April 7, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 7, 1888, TO APRIL 13, 1888.

BUSHNELL, GEO. E., captain and assistant surgeon. From Fort Preble, Me., to Camp Pilot Butte, Wyo.
STEPHENSON, WM., first lieutenant and assistant surgeon. From Camp Pilot Butte, Wyo., to Fort Verdi, Ariz.
MEARNS, E. A., first lieutenant and assistant surgeon. From Fort Verdi, Ariz., to Fort Snelling, Minn.
KNUDSEN, WM. L., first lieutenant and assistant surgeon. From Fort Snelling, Minn., to West Point, N. Y.
BORDEN, W. C., first lieutenant and assistant surgeon. From Fort Douglas, U. T., to San Antonio, Tex.
EDIE, G. L., first lieutenant and assistant surgeon. From San Antonio, Tex., to Fort Douglas, U. T.
S. O. 79, A. G. O., April 6, 1888

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 14, 1888.

PERCY, HENRY T., passed assistant surgeon. From Naval Academy, and to Hospital, Washington, D. C.
CRAWFORD, M. H., passed assistant surgeon. From Hospital, Washington, D. C., and wait orders.
PLINT, J. M., surgeon. From Fish Commission duty and to special duty at Smithsonian Institution.
PERSONS, R. C., surgeon. To duty in charge of Army and Navy Hospital, Hot Springs, Ark.
STONE, E. P., assistant surgeon. From further treatment, and to duty at Hospital, New York.
KINDLEBERGER, DAVID, medical director. From Hospital, Washington, D. C., and wait orders.

HOCHLING, A. A., medical inspector. To Naval Hospital, Washington, D. C.

HARMON, G. E. H., passed assistant surgeon. To duty at Naval Academy, Annapolis, Md.

STATE SANITARY CONVENTION OF PENNSYLVANIA.

A State Sanitary Convention will be held at Lewisburg, Union County, Pa., under the auspices of the State Board of Health, Thursday and Friday, May 17 and 18, 1888.

Lecture.

CARTWRIGHT LECTURES.¹ THE GENERAL PATHOLOGY OF FEVER.

BY WILLIAM H. WELCH, M.D.,
Professor of Pathology, Johns Hopkins University, Baltimore.

LECTURE III.

THE ETIOLOGY OF FEVER.

We considered in the last lecture the experimental evidence concerning the effects of increased bodily temperature. An advantage of the experimental over the clinical method of investigating this subject is that it enables us to study the effects of heat upon the whole body and its various functions without the intervention of disturbing factors, such as infection, which complicate the clinical analysis of febrile phenomena with reference to this question.

We found that animals may be kept at high febrile temperatures for at least three weeks without manifesting any serious symptoms. The only functional disturbances which could be attributed directly to the influence of the elevated temperature were increased frequency of respiration and quickened pulse. The rapid respiration was found to be due partly to stimulation of the skin by external heat and by the warmed blood, and partly to the action of the warmed blood on the respiratory centres. The quickened pulse could be positively referred to the effect of the warmer blood upon the heart itself. No definite relation could be established between the variations of arterial tension which occur in fever and the height of the temperature.

Although the experiments narrated showed that prolonged high temperature is an element in the causation of fatty degeneration of the heart, they also indicated that other factors, such as infection, are concerned in the production of this lesion. Moreover, experimental evidence was found in support of clinical facts showing that this alteration may exist without serious interference with the functions of the heart, so that the conclusion seems justified that failure of the heart's power in fever is less an effect of high temperature than of other concomitant conditions.

Of the other disturbances in fever we learned that the increased consumption of tissues can be explained only in relatively small part by the elevation of temperature. The lessened perspiration, the renal disorders, and the digestive disturbances (with the possible exception of constipation) are referable also chiefly to other causes than the increased temperature. Both experimental and clinical observations strongly support the view now widely accepted, that the disturbances of the sensorium which constitute so prominent a part of the group of so-called typhoid symptoms are dependent in far higher degree upon infection or intoxication, than upon the heightened temperature.

Although no attempt was made to analyze in detail the clinical evidence relating to the effects of high temperature attention was called to the fact that the absence of all serious symptoms in many cases of relapsing fever, and in the so-called aseptic fevers, in spite of prolonged high temperatures strongly support the conclusions derived from the experimental study of the effects of heat upon men and animals.

Even in fevers, such as typhoid fever and pneumonia, where the height of the temperature is undoubtedly a most important index of the severity of the disease, there exists no such parallelism between the temperature and the nature and the severity of the other symptoms as we should expect if these symptoms were caused by the increased heat of the body.

It was emphasized that the results of experimental investigations should not be permitted to control the treatment of fevers, more particularly the use of so-called antipyretic agents. These agents, whether hydrotherapeutic or medicinal, influence, as is well known, many functions besides reducing the temperature. I need only refer to the powerful influence, of cold baths upon the circulation and the nervous system, and to the action of antipyretic and other antithermic drugs upon the nervous system.

Reasons were given for assigning to hyperpyrexia and insolation a position separate from other febrile conditions in the discussion as to the effects of elevated temperature.

Before leaving this subject of the effects of increased temperature I wish to call attention to one consideration, which should, perhaps, influence our opinion on this much disputed question. Is it a matter of indifference so far as the effects of febrile temperatures are concerned in what manner the increase of temperature is brought about? We have seen that heat-regulation, heat-production and heat-loss are disturbed in fever, but, as experience shows, not always in the same manner or the same degree. In one case the incoordination of the regulating mechanism may be most apparent, the temperature fluctuating strangely up and down; in another case the heat-producing processes are excited to the utmost, and in another the circulatory changes in the skin, the vaso-motor disturbances, are the most prominent phenomena. Now this varying interplay of the factors which cause febrile rise of temperature doubtless corresponds to varying conditions of innervation, of structure and of function of certain tissues of the body. May we not reasonably suppose that these varying conditions of the tissues directly associated with the rise of temperature, may influence their tolerance of increased body heat? We have not the experimental or the clinical data which would enable us to give a definite answer to the question here propounded, and it would lead me too far from the theme of the present lecture to attempt to sift the equivocal evidence which might be gathered. I suggest this question, however, as one worthy of more attention than it has hitherto received.

I wish now to invite your attention to some considerations concerning the etiology of fever. In this era when etiological studies occupy the foremost rank in medical science, it will naturally be expected that a discussion of the general pathology of fever, even though it does not aim at completeness, will not leave wholly untouched the etiological aspect of the subject.

The general etiology of fever relates mainly to a consideration of the agents producing fever, the so-called pyrogenic substances. It is, moreover, only certain general characters of these agents which can be properly considered here. Most of the questions which at present engage so prominently the attention of physicians concerning the specific causes of individual fevers belong, of course, to the special etiology of fevers, and therefore, do not lie within the limits of

¹ Delivered at the College of Physicians and Surgeons, New York, April 12, 1888.

our subject. But even with these limitations we can not, in treating of the general etiology of fever, consider the febrile process so much in the abstract as we have done hitherto. We must come into closer contact with the individual forms of fever.

At the start it should be said that probably in no instance are we acquainted with the actual substance or substances upon which the febrile disorder of animal heat immediately and directly depends. We deal here, as elsewhere in medicine, not with direct, but with remote causes. But in no department of etiology have we advanced nearer the proximate causes than in many of the infectious fevers. To be convinced of the immense progress which has been brought about by the etiological study of fevers, let one pick up some of the older books on fevers, such as Percy's or Selle's,² with their endless divisions into sympathetic genera and species and their barren speculations. Percy, for instance, describes no less than one hundred and fifteen different kinds of fevers.

In all ages it has been customary to divide fevers into two great groups; namely, those which are secondary to some local cause, usually an inflammation, and those which cannot be explained by the presence of any local lesion. The explanation of the symptomatic seemed so much clearer than that of the essential fevers, that attempts have repeatedly been made to place all fevers in the symptomatic group. It is a curious fact that the two methods which have been of the greatest service in the study of fever, each, when first introduced, led to an entire misconception of the nature of fever. Boerhaave, who was the first to make any extensive use of the thermometer at the bedside, supposed that this instrument indicated a reduction of the bodily temperature during the febrile chill. He, therefore, taught that increasing frequency of the pulse, and not the elevation of temperature, is the constant and essential symptom of fever. If we accept De Haen's correction, which never became widely known, it was not until the middle of the present century that Boerhaave's error was overthrown. A no less serious misconception sprang from the study of the pathological anatomy of fevers in France during the early part of the present century. The exaggerated ideas of the immediate followers of Bichat as to what can be accomplished by pathological anatomy led them to the belief, for a long time widely accepted, that there is no such thing as an essential fever, and that all fevers are symptomatic of some local disease. This error of Broussais, one of the most influential and eloquent medical teachers of this century, is plainly traceable, partly to the fact that his autopsies were chiefly of typhoid fever, and partly to the belief that the lesions found at the autopsy suffice to explain all of the manifestations of the disease during life. But we need not stop to trace the fate of the various attempts to overthrow the doctrine of essential fevers. I have mentioned one attempt chiefly on account of the suggestive lessons it conveys, rather than from a desire to enter into historical details, which I have hitherto purposely avoided.

The division of fevers into symptomatic and essential fevers is one of undoubted practical utility, and is not likely to be abandoned. But it cannot truthfully be said that this popular classification has been of

much assistance in advancing our knowledge. Close inspection shows that the boundary lines between the two groups of fevers are vague and shadowy. Probably no one any longer believes that traumatic fever, the principal type of the symptomatic group, is due to increased production of heat in the seat of inflammation, which, acting like a furnace, was once thought to warm the whole organism, or to the irritation of nerves connected with the inflamed region. The opinion of Billroth and of Weber is now generally adopted, that traumatic fevers are caused by the absorption of pyrogenic substances from the inflamed district. Symptomatic fevers, as well as essential fevers, therefore, are dependent upon the presence within the blood of fever-producing agents. Many essential fevers, moreover, resemble the symptomatic ones in the existence of inflammation or necrosis at the portal, where there is reason to believe that the pyrogenic agents gain access to the general circulation. A distinction in these cases cannot be based on the ground that in symptomatic fevers only chemical substances, although possibly the products of bacteria, enter the circulation, and in essential fevers microorganisms invade the blood, for such a distinction would place cholera, and possibly tetanus and typhoid fever, among the symptomatic fevers. These considerations show how vague and unsatisfactory are the distinctions between symptomatic and essential fevers. Still, similar criticisms can be made of many of our artificial classifications, which nature is under no compact to observe, and we should undoubtedly be put to great inconvenience if we attempted to dispense with the epithets symptomatic and essential, as applicable to different forms of fever. There are, however, other points of view which seem to me more fruitful in the study of the etiology of fever than those embodied in these distinctions. I refer to the differences in the nature of fever-producing agents, concerning which our knowledge, although still very imperfect, has been materially increased within recent years. And here, again, we are greatly indebted to the results of experiments upon animals.

Much light has been shed upon the causes of a certain class of fevers by a series of experiments, which received their impulse from the important studies of Alexander Schmidt and his pupils upon the physiology of the blood. A particular direction was given to these experiments by the often-repeated observation that fever and other injurious effects may follow the transfusion of blood, especially when the blood of one species of animal is transfused into an animal of another species. In order to test the supposition that these bad symptoms are due to an excess of fibrin ferment, Köhler³ injected into the vessels of animals blood made rich in fibrin ferment and fibrino-plastic substance, and found that this blood, when injected in large amount into the jugular vein, causes sudden death by rapid coagulation of the blood in the right heart and pulmonary arteries, but when injected in smaller amount or in a different manner, produces a typical febrile attack bearing a close resemblance to that following the injection of putrid fluids. Angerer⁴ then found that a similar fever, although less intense and more gradual in its development, may be produced by the injection of blood into the peritoneal

cavity or the subcutaneous tissue, or even by an extravasation of blood. Although in these experiments it was believed that fibrin ferment is the pyrogenic agent, Edelberg⁵ was the first to produce fever and other symptoms of intoxication by the injection of this ferment, isolated according to Schmidt's method.

In the light of these experiments, it was to be expected that other ferments would be examined with reference to their pyrogenic power. Schmiedeberg⁶ discovered that injections of histozyme into the blood of dogs produce high fever, associated with general illness, and particularly with diarrhoea. The ferment to which Schmiedeberg has given the name histozyme he believes to be present normally in small amount in the body, and to be concerned in the disassociation of the nitrogenous constituents of the tissues. He concludes from his experiments that an excessive accumulation in the body of this normal ferment gives rise to fever, with increased metamorphosis of nitrogenous material. Schmiedeberg thinks it probable that the fibrin-ferment solutions employed by Edelberg in his experiments contained also histozyme, and that the pyrexia was due to the latter substance.

Following these observations concerning the pyrogenic power of fibrin ferment and histozyme comes the discovery by von Bergmann and Angerer⁷ that injections of pepsin and of trypsin into the blood of dogs causes a well-marked fever with characters like those of the other ferment intoxications described. A valuable calorimetric study of pepsin and trypsin fevers has been made by Wood, Reichert and Hare.⁸ These authors as well as Ott⁹ have demonstrated that it is not the pepsin and the trypsin ferments themselves which constitute the pyrogenic agents but some contaminating substance which seems to be a peptone. That peptones artificially prepared contain poisonous principles has been known for some time and Brieger¹⁰ has succeeded in isolating a crystallizable poisonous ptomaine, called pepto-toxin, from commercial peptone and from that formed by the artificial digestion of fibrin. This ptomaine, however, is not identical with the pyrogenic agent found by Ott, and by Wood and his colleagues in commercial pepsin. To this list of pyrogenic substances obtained from impure ferments may be added leucin, and according to Ott, papayotin and neurin which produce marked fever when injected into the blood in small quantity. The substance sold under the name of papoid possesses marked pyrogenic power when its filtered aqueous solution is injected into the blood. This substance contains principles belonging to the peptone or albumose group. Dr. Mall, Fellow in Pathology at the Johns Hopkins University, has isolated from commercial papoid a bacillus which in pure culture exerts a powerful peptonizing action on fibrin and on connective and elastic tissues. The bacillus itself is not pathogenic, but an albumose or some similar substance produced by its activity has pyrogenic power when injected into the blood.

It does not appear that any one has actually isolated the pyroxial agent from the various ferments employed in these experiments. Certainly no such agent has been obtained in a crystalline form, which

is the test of its purity, if we except Brieger's pepto-toxin, the pyrogenic capacity of which has not been established. It has been alleged that the fever-producing agent is the same in all of these ferment intoxications, but this has not been proven, nor does it seem probable.

On better grounds, it has been urged by von Bergmann and Angerer that all of the substances in the group of pyrexial agents now under consideration, cause fever by producing the same change in the blood. These authors claim that this change in the formation in the circulating blood of an excessive amount of fibrin ferment which leads either to coagulation or to stasis in the capillaries, particularly those of the lungs and of the intestines. One of the main arguments for this view is the fall of blood-pressure which von Bergmann and Angerer observed after injections of pepsin and of pancreatin, but this fall can be explained in other ways than by supposing that the pulmonary capillaries are occluded and, moreover, Wood, Reichert and Hare find that the blood-pressure often rises in the course of pepsin fever. It does not seem to me that we are any more able to explain in exactly what manner the pyrogenic substances act in this class of fevers than in other fevers. The idea, however, that the liberation of the fibrin ferment in abnormal quantity is capable of causing fever, finds support not only in experiments which have been mentioned, but also in the fact that injections of hæmoglobin solutions and of large quantities of water into the blood produce fever.

But you perhaps by this time have asked yourselves what bearing all of these experiments with various pyrogenic substances have upon the etiology of human fevers. They have in my judgment an important bearing on this subject. However obscure may be the explanation of the mode of action of these substances, however doubtful may be their exact chemical composition, they have certain common characteristics which are calculated to shed light upon the causation of some obscure febrile disorders of human beings. In the first place the members of this group of pyrogenic substances, if not identical with certain physiological ferments, are readily produced by them, quite independently of the action of bacteria or other microorganisms. In the second place some of these substances are present normally in small amount in the body and if their elimination is impeded or their formation is excessive, there is reason to believe that they become efficient causes of fever. In the third place these pyrogenic substances may be produced, again without the action of bacteria, in extravasated blood or by the abnormal disintegration of tissues, and if they are absorbed from these sources in such a condition or in so large an amount that nature cannot render them harmless, they are capable of producing fever. It is customary to call the morbid condition produced by the absorption of these substances ferment intoxication in analogy with the term putrid intoxication, applied to the diseases caused by the absorption of the products of putrefactive bacteria. The term ferment intoxication seems to me to imply more than our knowledge warrants, but it is not of much use to contend against names which have gained currency. It is probable that some of the pyrogenic agents in this group belong to the class of leucomaines, but our present information regarding these bodies does not justify any positive statements on this point.

Although the etiology of individual fevers does not belong to our subject I cannot forbear calling your attention to certain febrile conditions which seem to be produced by the accumulation of substances that are either normal constituents of the body or are the result of chemical processes differing but little from physiological ones.

To this category probably belongs the so-called aseptic fever first described by Genzmer and Volkmann.¹¹ These surgeons have established the fact that there are traumatic fevers not caused by the absorption of septic material and that severe injuries and wounds which pursue an entirely aseptic course are not infrequently associated with considerable elevation of temperature. This aseptic fever is usually to be observed with extensive wounds or injuries in which there is much lacerated tissue or extravasated blood to be disintegrated and absorbed. It occurs not only with wounds correctly treated by antiseptic methods, but also with subcutaneous injuries, particularly fractures of the large bones, where there can be no suspicion of the action of bacteria. Aseptic traumatic fever differs by such marked characteristics from septic fever, that there can be no doubt that the two types of fever are etiologically distinct. Aseptic fever has no prognostic significance; its only symptoms are the elevation of the temperature, which may mount to 104° (40° C.), or even 105.8° (41° C.), and the increased frequency of the pulse. The entire absence of all of the intoxication symptoms of septic and infectious fevers, such as the benumbed sensorium, the dry tongue and skin, the lessened secretion of urine, I have already referred to in confirmation of the belief that these symptoms are not dependent upon the rise of temperature. Genzmer and Volkmann assign as the cause of aseptic traumatic fever the absorption of substances resulting from the disintegration of the wounded tissues and of the extravasated blood and state that these substances probably do not differ markedly from those produced by physiological tissue metamorphoses. This explanation certainly has received decided support by the experiments which I have described in this lecture, a large part of which have been performed since the publication of Genzmer and Volkmann's article. It has been suggested that aseptic traumatic fever is a reflex neurosis and this suggestion cannot be absolutely rejected as a possible explanation, but for various reasons which cannot here receive further consideration, the usually accepted explanation is the more probable one.

An instructive case of ferment intoxication has been reported by Cramer.¹² There existed in a young woman a cyst the size of a goose's egg between the fibres of the semitendinosus muscle. The cyst was developed from a cavernous angioma and was filled with dark fluid blood. The patient had had fever for almost two years up to the day of the operation. The cause of the fever could not be discovered. Immediately after the removal of the cyst the fever stopped and did not return. In this case the cavernous structure of the cyst-wall accounts for the ease with which we must suppose a considerable quantity of the pyrogenic substance was continuously absorbed from the bloody contents of the cyst. The results of

Angerer's experiments already mentioned, enable us to explain the source of the fever in this case.

Another instance may be cited in which fever is probably to be explained by the accumulation within the body of products of normal metabolism. More or less fever appears to be a constant accompaniment of the agonizing method of treatment known as the Schroth cure. In this treatment the patient is kept for a number of successive days on dry food with scarcely any fluids. Both Bartels and Jürgensen,¹³ who have investigated the nutritive changes of individuals under this treatment, believe that the body becomes so poor in water that some of the products of regressive metamorphosis cannot be carried out of the system. This certainly seems very probable and if true it affords in the light of recent experiments an explanation of the accompanying fever.

I believe that good reasons can be adduced in support of the opinion that the febrile conditions sometimes associated with leucocythæmia, profound anæmias, and chlorosis belong to the group of fevers we are now considering. It is possible that some of the obscure ephemeral fevers are also to be included here. But to consider these febrile disorders in detail would lead us into the domain of special etiology upon which we have already, perhaps, encroached too far. My purpose has been to bring before your attention only a few clinical examples in illustration of the experimental results.

I think that you will agree with me in the conclusion that experimental and clinical evidence justify us in recognizing as a distinct group of pyrogenic agents substances which have no necessary connection with microorganisms and which are either not foreign to the healthy organism, or are readily formed by unorganized ferments from normal or abnormal constituents of the body. These substances may be described as homologous in distinction from the heterologous agents concerned in the production of septic and infectious fevers.

A class of pyrogenic agents of far greater clinical importance than those previously considered is formed by the products of microorganisms which in themselves are not pathogenic. A considerable number of bacteria which when inoculated in pure culture into the body are not capable of further invasion or of multiplication, produce in culture fluids and in dead animal or vegetable material poisonous substances often of great virulence. Exception may be taken to the description of these organisms as non-pathogenic, inasmuch as the products of their activity are poisonous, but the epithet pathogenic is usually assigned by bacteriologists only to such microorganisms as are capable of multiplication within the body. If we called all of the microorganisms pathogenic which produce poisonous ptomaines, we should have to include in this category a far larger number of the known species of bacteria than has hitherto been customary.

The best known and most important of the fevers produced by chemical products of saprophytic bacteria are those grouped under the name putrid intoxication. Until the introduction of the latest era in bacteriology by Koch, nearly all of the experimental work on the etiology of fevers related to the causation of the septic and putrid fevers. It is instructive with our present knowledge to follow the experiments on this subject from the period of Gaspard, Magendie and

¹¹ Genzmer u. Volkmann, Volkmann's Sammlung, No. 121.

¹² Cramer, Verhandl. d. Deutschen Gesellschaft f. Chirurgie, 13tes Congress, 1884.

¹³ Jürgensen, Deutsches Arch. f. klin. Med., Bd. I.

Sedillot up to recent times. What light has been shed upon the mass of contradictory and perplexing results of experiments with putrid fluids by the recent chemical and biological studies of putrefactive processes! Some of the putrid substances experimented with undoubtedly contained parasitic microorganisms, and others contained only obligatory saprophytes, some were rich in poisonous ptomaines and others were nearly devoid of them. The whole doctrine of the parasitic nature of infectious fevers seems to have hinged in the minds of some upon the determination of the question whether septic and putrid fevers are produced by the absorption of chemical substances or by the invasion of pathogenic bacteria. The ideas concerning putrid intoxication dominated at one time the whole field of fever etiology and were applied not only to septicæmia but to typhoid fever, typhus fever, yellow fever, in fact, to nearly all infectious fevers. Nor have the echoes of this period even now entirely died out.

Paum was the first to isolate from putrid materials some chemical substance or substances in tolerable purity, certainly free from bacteria. This substance, when injected into animals, produce symptoms of putrid intoxication. Subsequently, von Bergmann and Schmiedeberg isolated from putrefying yeast a poisonous crystalline substance, their celebrated sepsin. For a time the opinion prevailed that this sepsin was the source of all putrid intoxications. Thanks to the investigations of Nencki and others, and particularly of Brieger, we now know that many alkaloidal substances can be separated from putrefying materials. Some of these so-called cadaveric alkaloids or ptomaines are poisonous, fever-producing, others are harmless. There is no reason to suppose that the list of the ptomaines of putrefaction has been exhausted, nor is it necessary to believe that all of the poisonous constituents of putrefying materials are of an alkaloidal nature.

Most of the bacteria concerned in ordinary putrefactive processes are purely saprophytic. They are incapable of multiplication in the living animal tissues. In a mixture of putrefactive bacteria it is not, however, uncommon to find genuine pathogenic or parasitic bacteria. It was from such sources that the bacilli of mouse septicæmia and of rabbit septicæmia (Koch) were obtained. The bacilli of malignant œdema is also often found in the early stages of post-mortem decomposition.

There is, of course, no doubt that the absorption of the chemical products of putrefaction may produce fever with septic symptoms quite independently of the penetration and multiplication within living tissues of bacteria.

Here belong certain cases usually described as septic, in which fever and other bad symptoms subside upon the thorough cleansing and disinfection of a foul wound or of a puerperal uterus. The majority of cases of septicæmia are not to be included here, for they depend upon the invasion of pathogenic bacteria. But excluding the cases of genuine septicæmia there remain the putrid intoxications which result from the absorption of poisonous substances produced in necrotic or disintegrating tissues, or exudations, or extravasated blood by the action of purely saprophytic bacteria. The ideas which I have expressed on this subject are now so generally admitted that they require no further elucidation.

It is probable that fever with symptoms of intoxication, although generally of a much milder nature than in the class of cases just considered, may be produced by abnormal fermentations and putrefactions caused by saprophytic bacteria in the alimentary canal. But here the essential morbid conditions seem to be abnormalities in the gastric and intestinal contents, due partly to the character of the ingesta but chiefly to alterations of the digestive juices.

Fermentative and putrefactive bacteria are normally present in the intestinal canal and have abundant opportunities to gain access to this situation. The number, however, which can multiply and thrive there is quite limited, for under normal conditions, according to Escherich, only such bacteria can multiply to any extent in the intestinal canal as are capable of growing with little or no oxygen and of deriving their nourishment from the anaerobic fermentation of the food supplied to them in this situation.

Of a far more serious nature are the putrid or ptomaine intoxications which result from the ingestion of substances which have undergone outside of the body putrefaction or changes which lead to the formation of poisonous ptomaines. To this group of cases belong at least many of the instances of poisoning which have been caused by eating certain kinds of meats, sausages, fish, cheese, etc. In some of these instances poisonous ptomaines have been isolated from the suspected substances, but we know scarcely anything of the microorganisms which are concerned in their production.

It is important to bear in mind that it is not stinking putrefaction alone which gives rise to poisonous products. Brieger has found that such products may be absent in very advanced decomposition, and that in general the most virulent products are formed in the early stages of putrefaction. We know, furthermore, that putrefaction and fermentations differ in the character of their products. There are differences according to the kind of bacteria present, according to the substances decomposed and according to various other conditions such as the presence of oxygen, the temperature, etc. This is not the proper occasion to discuss these details.

Enough has been said to prove that we are justified in recognizing as a second class of pyrogenic agents substances which are the products of bacteria, in themselves not pathogenic. These pyrogenic agents may be formed on or within the body or they may be produced outside of the body. I would not, by any means, have you infer that it has been proven in all of the special examples which I have mentioned that the bacteria involved are not pathogenic or capable of multiplication within the living tissues. We have not sufficient knowledge to assert or to deny this in every instance, but I do not think that it is likely exception will be taken to the classification which I have adopted for most of these cases. As has repeatedly been mentioned, our purpose here is not an analysis of individual cases of fever, but an attempt to classify systematically the various pyrogenic substances.

We come now to the third and most important group of fever-producing agents, the pathogenic microorganisms. So overshadowing is their importance that it has been claimed that they are the sole causes of fever. In contrast with former times it is no longer the symptomatic fevers whose etiology is clearest. We have much more definite ideas as to the

mode of production of some of the essential fevers which were once the most obscure, than we have of symptomatic fevers. It does not seem to me worth while to go over the chain of evidence which establishes the doctrine that the infectious fevers are caused by microorganisms. There is probably no one who has thoroughly investigated the subject and is competent to form an opinion on it who does not to-day admit that a number of infectious diseases have been proven to depend upon specific microorganisms, and that it is a logical inference that all infectious diseases are caused by parasitic organisms.

It is not germane to our subject to enter into a nomenclological or biological description of the different species of pathogenic organisms which are causes of febrile diseases. The only question which concerns us in this consideration of the general etiology of fever is how the microorganisms produce fever. Are they themselves the pyrogenic agents, or do they produce chemical substances which are pyrogenic? A number of other possibilities might be mentioned. These and similar questions have suggested themselves to investigators since the beginning of any knowledge of parasitic microorganisms. Our information is far from sufficient to enable us to answer these questions in a positive manner, and still we are not left wholly to vague surmises in attempting to form some sort of an opinion.

That bacteria can produce mechanical effects by plugging up capillaries, and in other ways, is certain; but the wide differences presented by the various infectious diseases cannot be reconciled with the idea that pathogenic bacteria act chiefly by mere mechanical interference with the fluid and the solid constituents of the body. Notwithstanding the fact that Stricker and Albert succeeded in producing fever by the injection of starch granules into the blood, probably no one will be inclined to attribute the pyrogenic activity of bacteria in any considerable extent to occlusion of bloodvessels.

In a certain number of infectious diseases, particularly of animals, bacteria are present in such enormous number in the blood and tissues that some are inclined to refer the disastrous effects of the organisms to the withdrawal of oxygen and other nutritive pabulum from the cells of the body. So far as the appropriation of oxygen is concerned, this idea is not supported by the results of most of the examinations of the blood in cases of anthrax. This explanation was more popular in the early days of bacteriology than it is at present, and at the best its value is limited, for it cannot be applied to a large number of infectious diseases, such as cholera or typhoid fever, where the circulating blood is not largely invaded by the parasites. Furthermore, it is not clear how the appropriation by bacteria of nutriment intended for the tissues would help us to explain the production of fever.

It has been suggested that the increased temperature in infectious fevers may be explained by the heat produced by oxidation or other chemical changes in the microorganisms themselves. But this is not at all a satisfactory explanation. Not only is the quantity of heat which can come from this source in all probability very small compared with that constantly produced in the body, but such an explanation of febrile rise of temperature is not in harmony with what we know concerning the mode of production of fever (see Lecture I).

The failure to explain the pathogenic power of bacteria in these and similar ways led to the supposition that the morbid activity of pathogenic bacteria is exerted chiefly by means of injurious chemical products. The demonstration of such products leaves no room for doubt as to the correctness of this supposition for some infectious diseases. This explanation is probable for most such diseases, but experience has shown that it is particularly dangerous to indulge in hasty generalizations in this department of medical science.

Sterilized and filtered cultures, particularly old cultures, of various pathogenic bacteria, are capable of producing fever and other symptoms when injected into the blood or tissues. This, of course, makes it evident the bacteria in question give rise to poisonous substances. It is necessary to distinguish between the intoxication produced by the injurious products of bacteria and the infection caused by the multiplication of the microorganisms within the body. That this distinction may be readily overlooked is shown by the recent experiments with the inoculation into animals of pure cultures of the typhoid bacillus. Small quantities of these cultures may be inoculated without any apparent effect. If, however, larger quantities are injected into the veins or the peritoneal cavity of a rabbit, the animal dies in a short time, and the characteristic bacilli are found in the blood, spleen and elsewhere. It was supposed Fraenkel and Simmonds,¹⁴ to whom we owe this latter observation, that actual infection took place, but it has been demonstrated by Strothmann and by Beumer and Peiper,¹⁵ that under these circumstances no multiplication of the injected bacilli occurs, and that the same results may be obtained by the injection of sterilized typhoid cultures.

The isolation in a chemically pure state of the poisonous products of pathogenic bacteria encounters great difficulties, and we owe to Brieger¹⁶ nearly all that has been accomplished in this direction. Two substances which he has obtained from cultures of pathogenic bacteria are of great interest. Brieger isolated from pure cultures of the typhoid bacillus a very poisonous ptomaine, or toxine, as he prefers to call this group of substances. He has given to it the name typho-toxine. It may be somewhat significant that he failed to find typho-toxine in a culture which had stood for twenty-four hours at a temperature of 102.2° (39° C.). The injection of typho-toxine into guinea-pigs produced great muscular weakness, diarrhoea, increased frequency of pulse and of respiration, and death. Nothing is said as to the effect upon the temperature of the animal.

A toxine has been isolated by Brieger in a crystalline form from an impure culture of the tetanus bacillus. This substance, called tetanin, produces when injected into animals the characteristic symptoms of tetanus.

It is evident that these important discoveries render far more definite than was formerly possible the belief that bacteria produce fever by means of their chemical products.

A dangerous influence exerted by poisonous ptomaines is that under their agency the power of the body of resisting the invasion of various microorganisms may be impaired or overcome. Thus Wyssokowitsch

¹⁴ Fraenkel and Simmonds, Die Aetiological Bedeutung des Typhusbacillus, Hamburg und Leipzig, 1886.

¹⁵ Strothmann, Zeitschrift f. Hygiene, Bd. 1, p. 465. Beumer u. Potper, Ibid, 490.

¹⁶ Brieger, Untersuchungen über Ptoinae, Berlin, 1886.

has shown that the immunity of some animals against certain species of bacteria may be destroyed by ptomaine poisoning.

In order to observe the effects upon the temperature I have injected into rabbits sterilized cultures of the typhoid bacillus. Injections of very small quantities of these cultures produce no effects; somewhat larger amounts cause a rise of temperature, without other marked symptoms; still larger quantities produce increased temperature, diarrhoea, weakness, and other manifest symptoms of severe illness, but the animal may recover; relatively large amounts are followed by fall of temperature, grave illness and death. I have also obtained results similar to those of Siroitiuin, who inoculated two rabbits with the same amount of a typhoid culture. In one rabbit fever developed and the animal recovered; in the other the temperature fell after the injection, and the animal died. This certainly does not indicate that the rise of temperature in itself is an unwelcome attendant of intoxication with the poisonous products of bacteria. My experience certainly showed that the animals were more likely to die after injection of typhoid cultures when the temperature fell than when it rose, independently of the quantity of material injected. One is reminded here of the very malignant cases of typhoid fever reported by Fraentzel and others, in which the temperature throughout a great part of the disease was sub-febrile, or even at times sub-normal.

In no disease is the dependence of the febrile paroxysm upon the presence of bacteria so apparent as in relapsing fever, where, according to the statements of most, although not of all, observers, the spirilla appear in the blood at the beginning of a paroxysm and disappear at the end. Whether or not here and in malaria the pyrogenic agent is a chemical product of the microorganisms causing the disease we do not know.

I must content myself with having brought before you evidence showing that at least in some of the infectious fevers the specific bacteria produce pyrogenic substances. We have no right to say that this is the only way in which pathogenic bacteria can cause fever.

We have considered now three groups of agents concerned in the production of fever; namely, first, unorganized ferments and other relatively homologous substances; second, ptomaines and other chemical products of saprophytic microorganisms; third, pathogenic microorganisms and their chemical products.

It is not to be understood that these groups correspond to sharply defined classes of fever-producing agents. The same substance may be produced by the action of unorganized ferments as well as by saprophytic bacteria or by parasitic bacteria; hence we may find the same fever-producing agent in each of the three groups. As has already been mentioned, our knowledge does not justify us in regarding these various substances as the immediate and direct pyrogenic agents. The epithet pyrogenic is applied to them only by a certain latitude or signification. It is possible that these various substances which we are in the habit of describing as pyrogenic, may produce in the body some common change which gives rise to the real fever-producing agent. This is the view of von Bergmann and Angerer, who believe that this common change is a liberation of fibrin ferment by destruction of leucocytes. While we cannot consider this view as more than a hypothesis, it is nevertheless

well to remember that apparently heterogenous substances which are usually designated as pyrogenic may produce similar changes which are to be regarded as the real source of the febrile disorder or animal heat. But notwithstanding these limitations and these elements of uncertainty it seems to me that some such classification as that suggested of the agents producing fever is more useful than that usually employed in the discussions of the etiology of symptomatic and of essential fevers.

There is one point which must be impressed upon every one who makes many experiments with pyrexial agents. This is, that once in a while a substance of undoubted pyrogenic power causes a fall instead of a rise of temperature. This occurs frequently when the substance is injected in large quantity, and under these circumstances there is usually produced a condition of collapse. But in exceptional cases the same dose which will cause in one animal a rise of temperature, may give rise in another animal of the same species to a distinct reduction of temperature. In these latter cases there must be some idiosyncrasy on the part of the animal. Aronsolin¹⁷ refers this unusual phenomenon to some peculiarity of the heat-centres of the brain and he draws an interesting parallel between this contrary effect of pyrogenic substances and the exceptional cases in which antipyretic drugs give rise to elevation instead of lowering of temperature.

The causes of fever which we have thus far discussed, have been substances which exert a pyrogenic effect when introduced into the circulation. We suppose that these substances act in some way upon the nervous system, but whether or not this action is a primary one it is impossible to say. Even if we assume, as it often done, that these substances incite directly in the blood and tissues chemical changes which lead to increased production of heat, we must still have recourse to some action upon the nervous system as has already been sufficiently set forth in the previous lecture.

It cannot be doubted that fever may be caused by other agencies than pyrogenic substances present in the blood or tissues. The effects of exposure to external heat have already been considered. We found experimental evidence in support of this view ably advocated by H. C. Wood, that in typical cases of thermic fever or sunstroke, the strain placed upon the heat-regulating centres by exposure to excessive heat, results in paralysis of these centres with rapid elevation of the external temperature.

The cause of the elevation of temperature in tetanus is not altogether clear. In this disease the temperature may vary but little from the normal, but it is not uncommon to find excessive elevation of temperature toward the termination. Temperature of 113° (45° C.), or more have been recorded. The idea would naturally suggest itself that the rise of temperature is due to the tetanic muscular spasms, which we know to be accompanied by production of heat. Leyden was led to adopt this explanation by the results of experiments made upon animals. He succeeded by producing violent tetanic contractions of the muscles of a dog in raising the internal temperature in the course of one hour and a half from 103.3° (39.6° C.) to 112.6° (44.8° C.). Clinical observations, however, do not support the supposition that the hyperpyretic

¹⁷ Aronsolin. Deutsche Med. Wochenschrift, 1888.

temperature of tetanus are dependent upon the muscular contractions. In spite of violent and prolonged tetanic spasms the internal temperature may remain normal or be but slightly elevated. There is a decided similarity between the hyperpyrexia of tetanus and that which occurs in rheumatism and some other diseases, particularly in affections of the central nervous system, and it certainly seems probable that in all of these cases there is a profound disturbance of the heat-regulating centres. As the elimination of urea in tetanus is not excessive, we find additional reason to separate tetanic hyperpyrexia from ordinary febrile conditions. Recent investigations of the etiology of tetanus have rendered it certain that at least some forms of this disease are caused by infection with a special microorganism. This has been demonstrated not only in the tetanus of animals but also in that of human beings. The tetanus bacillus has been found widespread in the ground in Germany, and I find it abundant also in the ground in Baltimore and its neighborhood. In experimental tetanus the specific bacillus, which has not yet been obtained in perfectly pure culture, develops chiefly in the tissues near the seat of inoculation and does not invade other parts of the body and the blood to any great extent. This indicates that the symptoms are referable chiefly to poisoning by some chemical products of the specific microorganism. As has already been mentioned, this view is sustained by Brieger's discovery in cultures containing the tetanus bacillus of a peculiar ptomaine which he has called tetanin, and which produces tonic spasms of the muscles. It is therefore reasonable to believe that the hyperpyrexia of tetanus is caused by the action of poisonous products of the tetanus bacillus on the nervous centres concerned in temperature-regulation. Our present knowledge, however, does not warrant us in asserting that all forms of tetanus in human beings are of an infectious nature.

In the first lecture of this course, evidence was presented to show that pyrexia may be caused by affections of the nervous system without the agency of any pyrogenic substance. It may jar upon the sensibilities of some to call this form of pyrexia, fever; but this hesitation can be due only to the idea that symptoms which are referable to infection or intoxication are essential to the conception of fever. In my judgment, we shall be led into confusion if we attempt to incorporate into our definition of fever more than properly belongs to the febrile disorder of animal heat, and from this point of view there can be no impropriety in designating as fever the pyrexia dependent directly upon affections of the nervous system.

It is not necessary to repeat here the conclusive experimental evidence for the existence in the nervous system of centres or regions which control the dissipation of heat, and the chemical processes concerned in the production of heat. Those who are not much impressed by experiments upon animals can hardly fail to be convinced by the clinical evidence which demonstrates that lesions of the nervous system may cause elevation of temperature which cannot be referred to the action of any pyrogenic substance. Such evidence must, of course, be collected from cases where the fever cannot be explained by inflammation, bed-sores, or other lesions which can give rise to absorption fever. W. Hale White,¹⁸ in the interesting

article already referred to, has collected a number of cases of tumor, hemorrhage, softening, sclerosis, injury, and functional disturbance of the spinal cord and brain, in which the pyrexia or hyperpyrexia is to be explained only by the lesion of the nervous system. The number of such cases might be considerably increased. These cases show that lesions of the cervical part of the cord, of the pons, of the corpus striatum, and of the neighboring white matter are most likely to be associated with high temperature, but the cases hitherto reported hardly justify positive statements as to the exact situation in man of thermically active nerves or regions in the brain and spinal cord. As might be expected, not only focal lesions, but also diffuse diseases, such as occur in general paralysis of the insane, locomotor ataxia, multiple sclerosis, may give rise to pyrexia, which sometimes assumes the form of temperature crises. It is in harmony with what we know of other disorders of the nervous system to find that not only demonstrable anatomical lesions, but also functional disturbances, may produce nervous pyrexia. Such functional disturbance furnishes the most probable explanation of the singular and erratic elevations of temperature which have been occasionally observed in hysteria.

A question which merits more consideration than it is possible to give to it on the present occasion relates to the possibility of the occurrence of fever as a reflex neurosis. The advance in our knowledge of the etiology of traumatic and inflammatory fevers has pushed aside almost wholly the old doctrine of irritative fever. There are, however, cases of fever where still the simplest and apparently most rational explanation of the causation is peripheral nerve-irritation. As examples, may be mentioned the fever resulting from teething in children, that sometimes accompanying the passage of gall-stones or urinary calculi, and that occasionally following the insertion of a catheter into the urethra. It must be admitted that the evidence on this point is not conclusive. Especially is there lack of satisfactory experimental evidence. Electrical irritation of the exposed sciatic nerve is, under ordinary circumstances, followed by a moderate fall of temperature, although Ott¹⁹ finds that in atropinized cats such irritation is followed by a decided rise of temperature. But these experiments cannot be held to weigh for or against the doctrine of irritative fever. Observations on human beings indicate that peripheral nerve-irritation, if ever a cause of fever, is so only in certain situations, and under certain forms of stimulation and in certain individuals. In infants temperature-regulation is more labile than in adults, so that it may be that nerve-irritation can more readily disturb the temperature in the former than in the latter. The chief controversy as to the question now before us has been as to the explanation of certain forms of urethral or catheter fever. It cannot be doubted that a large number, probably most, of the cases of so-called urethral fever are instances of genuine absorption fever. Even if we exclude all cases with diseased kidneys, or with cystitis or other inflammatory disease of the urinary passages, there remains a certain number of cases in which the gentle insertion of a disinfected catheter is followed by distinct febrile reaction. It seems unwarrantable to assume that in all of these cases the catheter has caused a laceration of the urethra, through which pyrogenic substances

¹⁸ W. Hale White. The Theory of a Heat-Centre from a Clinical Point of View. *Guy's Hospital Reports*, Vol. 42, 1884.

¹⁹ Ott. *Therapeutic Gazette*, August, 1887.

are absorbed. What is the nature, and whence the source of these substances? In the cases now under consideration they can be sought only in the normal urine, and of their existence there no proof has been afforded. In these cases, it is certainly very difficult to understand how the fever can be interpreted as due to the absorption of some pyrogenic agent, and, failing this explanation, the idea that the fever is dependent upon nerve-irritation is most plausible.

I have now presented to you an imperfect survey of the general etiology of fever. The attempt has been made to classify the leading causes of fever, but it can not be claimed that every variety of fever can be assigned to one of these groups of causes. Our knowledge of the etiology of special fevers is still too imperfect to warrant any such generalization. This is an attractive field for much patient investigation. I need only remind you of the uncertainty which still pertains to the causation of many of the fevers of warm countries. There is reason to believe that there remain yet to be differentiated etiologically specific types of fever which occur among us, and particularly in our Southern States. It may be that increasing knowledge will necessitate the recognition of varieties of pyrogenic agents entirely distinct from any with which we are now familiar. It is certain that future investigations will add clearness and precision to our ideas of the nature and mode of action of causes of fever which at the best we can now understand only imperfectly.

I cannot conclude this course of lectures without saying a word on a subject which must engage the attention of every one who gives much thought to the nature of fever. What is the significance of fever is a question which thrusts itself upon us no less than it has upon physicians in all ages. Unfortunately, we cannot to-day any more than could our predecessors give other than a speculative answer to this question. There have been in all ages enlightened physicians who have held the opinion that fever is a process which aids in the elimination or destruction of injurious substances which gain access to the body. Under the influence of ideas which sought in increased temperature the origin of the grave symptoms of fever, we have in recent times in great part lost sight of the doctrine once prevalent, that there may be in fever a conservative element. There is much which speaks in favor of this doctrine. The real enemy in most fevers is the noxious substance which invades the body, and there is nothing to prevent us from believing that fever is a weapon employed by nature to combat the assaults of this enemy. The doctrine of evolution indicates that a process which characterizes the reaction of all warm-blooded animals against the invasion of a host of harmful substances has not been developed to such an extent, and is not retained with such pertinacity without subserving some useful purpose. This is a point of view from which many pathological processes can be regarded with advantage. Even suppuration, which one does not generally look upon as a beneficent provision, is a most important instrument of nature in forming a barrier against general infection of the body with certain microorganisms. It is impossible, with our present knowledge, to say in exactly what way fever accomplishes a useful purpose. There are facts which suggest that in some cases of fever the increased temperature as such may impair the vitality or check the virulence of pathogenic micro-

organisms, but there are many circumstances which make it difficult to suppose that this is the agency by which fever usually exerts a favorable action. The supposition seems to me more probable that the increased oxidation of fever aids in the destruction of injurious substances. According to this view the fever-producing agents light the fire which consumes them. It is not incompatible with this conception of fever to suppose that the fire may prove injurious also to the patient, and may require the controlling hand of the physician. Time will not permit me to elaborate further the ideas here suggested. In the course of these lectures some facts have been presented, and others might be drawn from clinical and experimental observations, which favor the hypothesis that fever is in a certain sense a conservative process. Unproven and intangible as the hypothesis may seem to some, no apology is needed for bringing to your attention a conception of fever in favor of which much can be adduced, and which, if true, is of fundamental importance, both theoretically and practically.

Original Articles.

FIFTY CASES OF SCARLET FEVER.¹

BY HENRY JACKSON, M.D.

I wish to present to the Section a short account of these cases, as an epidemic of this size always gives one an opportunity of making some interesting observations.

These cases occurred in the North End of Boston during the months April to October.

April	4	
May	3	Very mild.
June	3	
July	3	More severe.
August	10	Much more severe, with throat trouble.
September	24	Severe type with diphtheria.
March	2	
Total,	50	

Of these cases thirty may be characterized as of a mild type. Prodromal period short, usually twelve to twenty-four hours; vomiting almost always present; headache and malaise; usually more or less complaint of sore throat. In cases where an examination at the early stage was possible, I did not find the appearance of the throat sufficiently characteristic to warrant a diagnosis of scarlet fever merely from this symptom. In no case were convulsions seen. The period of efflorescence lasted from twenty-four hours to four days, rarely longer. Temperature not high. Many of the children wished to be about the house, and were with difficulty kept in bed, even during the height of the eruption. Vomiting ceased in most cases on the appearance of the eruption; occasionally it continued until convalescence was established.

As the other cases presented some points of particular interest, I will give you them more in detail. In two cases there was no eruption and yet the diagnosis of scarlet fever seems to be fairly well justified.

Katharine McCoy, fifteen years. Slept in a bed with two children who had well-marked eruption. She had a moderate fever, headache, malaise, pharyn-

¹ Read before the Suffolk District Medical Society, Section for Clinical Medicine, Pathology and Hygiene, February 8, 1888.

gitis and tonsillitis (not follicular). Well on the fifth day. No sequelae.

Annie McLaughlin, eleven years. Lived in the same lot that three children lived in who had scarlet fever. No eruption, slight pharyngitis, mild febricula of a few days' duration. Of course scarlet fever would not have been considered except for the other well-marked cases. Under the circumstances it seems to me highly probable that her symptoms may have been due to scarlet fever.

Raphael Bornstein, four years. Acute lobar pneumonia on seventh day. Course of the scarlet fever mild and of no special interest.

In four cases convalescence was delayed by supuration of the parotid gland. One case was complicated with measles.

Mary McCalligan, two years. Well-marked eruption of scarlet fever; severe catarrhal pharyngitis. On the fifth morning the eruption had faded, and the temperature was normal; that night temperature 102° , and body covered with a very fine punctate rash. Next day an abundant and well-marked eruption of measles. Catarrhal inflammation of eyes, nose and bronchi. Child very sick for a week. Pulse 160, temperature 103° to 104° , respiration 45. Lobular pneumonia in right front. In the latter part of the attack of measles, the skin presented a very curious appearance, as the bright red papules of the measles were covered by the dried scales left by the scarlet fever. Urine showed a small trace of albumen and a few casts. Complete recovery.

One case only had very high fever.

Nettie McCullough, six years. Eruption well-marked; temperature 104° to 105° for several days; pulse 140; stimulants ordered. Disease was followed by leucorrhoea of several weeks' duration; and one month after the attack of scarlet fever she had articular rheumatism.

One case had oedema during convalescence without any apparent renal disease.

Nellie Connors, six years. Mild fever; no vomiting, slight pharyngitis; during convalescence very marked anæmia, slight oedema of face, hands and feet. Careful and repeated examination of the urine gave a negative result as to the existence of renal disease. I attributed the oedema to the anæmia, but found that Strümpell spoke of oedema as occurring after scarlet fever, dependent upon molecular change in the walls of the bloodvessels.²

Two cases of acute Bright's disease. In the second and third weeks respectively, after the onset of the scarlet fever, urine smoky in color, contained one-fourth per cent. of albumen, large numbers of casts of various kinds. In each case headache, vomiting and general oedema. Complete recovery in each case.

The following case is one of great interest; and I fortunately have complete notes of the case, as the child was under the care of a trained hospital nurse.

R. F., nine years. November 4th. Eruption appeared, very light; pharyngitis marked. For three days pulse and temperature very high. On tenth day temperature normal, and pulse 100. During convalescence pulse very slow and irregular, frequently intermittent; no murmur detected. Under small but frequent doses of tincture of digitalis and brandy pulse became rapid, regular and of good strength.

November 29th. Sudden rise of temperature, with

swelling of the glands of the neck. Examination of the urine negative.

November 23d. (Three weeks after the onset of the fever.) Passed very little urine; vomited several times; slight oedema. Rise of temperature. Urine smoky; one-quarter per cent. of albumen sediment, that of acute parenchymatous nephritis. Gradual improvement in general symptoms and in the character of the urine until December 1st.

After having passed a remarkably good day, the child woke on the night of December 1st, and complained of severe frontal headache. Vomited several times during the night. These symptoms continued through the forenoon of December 2d. Small dose of morphine, one-sixteenth, given on account of headache.

In the afternoon became somnolent, and soon completely unconscious. At 4 p. m., respiration 20, pulse 130; pupils not noted by the nurse. Diagnosis of opium-poisoning was made by a physician, and treatment ordered accordingly.

I saw the child at 5.30. Found respiration 18, irregular in rhythm; pupils normal. He was inclined to sleep, but when aroused, answered questions intelligently. An hour later, roused with difficulty; when addressed, did not answer the question, but counted twenty-six, twenty-seven, twenty-eight, twenty-nine, thirty. He never counted more than thirty, always began with twenty-six, and sometimes repeated the number twenty-six several times without counting further.

At 8 p. m., perfectly unconscious; respiration stertorous, irregular, two to four respirations being followed by a long pause, etc.; pulse 120; pupils regular and of normal size; convulsive twitching of the right side of the face and right arm, which lasted for about three-quarters of an hour; no paralysis.

Next morning perfectly conscious; showed no symptoms, and had no remembrance of the events of the previous day.

For several days the urine was very scanty, contained a large amount of blood and albumen, and many casts. From this time on gradual improvement, until convalescence was completed. The distinctly localized convulsive twitching seemed to point to some lesion of the cortex; but I think that the rapid recovery makes it more probable that all the cerebral symptoms were dependent upon uræmia. There was at this time a slight systolic souffle at the apex, but no enlargement of the heart.

January 25th. Boy stout and well; no murmur.

Eight cases had severe diphtheritic inflammation of the throat; that is to say, there was extensive ulceration, with membranous exudation on the tonsils and uvula, or pillars of the fauces. Cases in which several small gray patches were seen on the tonsils are not included in this list.

Flint, Henoch and Strümpell say decidedly that, though the disease is anatomically identical with the condition usually found in diphtheria, the disease is etiologically distinct. Eichhorst considers it at least possible that the condition is due to true diphtheria implanted upon the already existing scarlet fever.

The chief arguments that the disease is not diphtheria are clinical in nature; namely, (1) Invasion of the larynx is rare; (2) paralysis rarely follows; (3) the disease is not so fatal as true diphtheria.

So far as any conclusions can be drawn from so

small a number of cases, all of these arguments are refuted by the cases which came under my observation.

In only one case did the diphtheritic inflammation appear early in the course of the scarlet fever; in the others the membrane was observed on the third or fourth day, or during the stage of desquamation.

One case died from invasion of the larynx by the diphtheritic membrane. In a second case there was probably membranous laryngitis, as evidenced by hoarseness and embarrassed respiration. The child died apparently from asthenia. I doubt if tracheotomy would have been of any avail, even if the parents had assented to the performance of the operation.

Two cases died of paralysis of the heart; one when convalescence was perfectly established, and one when the child was apparently improving rapidly.

The mortality was large, as four out of eight (50%) died.

Cases of especial interest are the following:

Millie Hackett, three years. When first seen there were remains of a rash of scarlet fever; on both tonsils and uvula a dirty gray membrane, which spread in a day or so to the pillars of the fauces. Parts bled if touched. Another physician was called, as my prognosis was grave. On the eleventh day I saw the child playing in the street. No ulceration in the pharynx. On twelfth day, sudden death from paralysis of the heart, according to the account given by the family.

Johanna Molineux, two and a half years. Brother of the patient had a mild attack of scarlet fever eleven days previously. Patient had a mild attack without marked pharyngitis. Fifth day, tonsils much swollen. In the course of a few days both tonsils and uvula were covered with membrane; lips and edges of nostrils ulcerated and bleeding. Thirteenth day, voice hoarse and almost inaudible; respiration somewhat embarrassed. Fifteenth day, death, without any preceding dyspnoea. Trace of albumen and a few casts in the urine.

Daniel Shields, five years. When first seen desquamation was going on; emaciation extreme; voice whining; ulceration of the edges of lips and nostrils; membrane on both tonsils and uvula; abscess below right ear that contained thin, bloody, foul-smelling pus. Treatment: locally, iodoform; internally, corrosive sublimate (gr. $\frac{1}{10}$ every hour), whiskey and eggs. Perfect recovery.

Three cases occurred in one family by the name of O'Brien. Hygienic surroundings good.

September 14th. Louisa, eleven years. Malaise; slight pharyngitis; rash, which lasted twenty-four hours. Second day, perfectly well. No sequelae. No desquamation.

September 14th. Mary, nine years. Eruption very full and bright. Third day, membrane on uvula and pillars of the fauces; mucous membrane of lips ulcerated and bleeding. In the course of a few days, foul ulcer on right elbow, ulcer of genitals and perineum. Sixth day, right knee red, swollen and tender. Next day same symptoms in left knee and left wrist. The disappearance of the latter symptoms in two days, under the use of salicylic of sodium made the diagnosis of rheumatism probable. Sudden death on tenth day.

James, three years, and Anne, four years. Both taken sick September 17th. In both cases eruption

intense; face much swollen, so that the eyes were partially closed; oedema of hands; urine contained a trace of albumen and a few casts. On third and fourth days respectively a membrane appeared on the tonsils and uvula. Both recovered completely.

The oedema in these cases was apparently due to the intensity of the eruption, as in neither case did the examination of the urine warrant the diagnosis of Bright's disease. Two other children that slept in the same room were not sick. It is an interesting fact that during the height of the disease the mother was confined, and convalesced without having any puerperal fever. She had no doctor or nurse.

SUMMARY.

Of these fifty cases, four died (*one in twelve*), all of diphtheria. These four cases are the only ones that died in my district, of scarlet fever; from April to January, the total number of cases being eighty-eight. This gives a mortality of *one in twenty-two*.

It has been interesting to me, and very satisfactory, to find that I have not been called to a single case of scarlet fever in a family which I had attended previously for any other disease. Of course it was impossible for me to think of changing my clothes, or even disinfecting the hands, before attending other cases.

The new cases visited each month average in my district two hundred.

The eight and only cases of diphtheria, all occurred in three weeks, and represented one-third of the total number visited in the three weeks.

Treatment. In mild cases expectant. In cases with high fever, tepid sponge baths and antipyrine. In cases with diphtheria, brandy and tinctura terri chloridi.

TYPHOID AND MALARIAL FEVER IN BOSTON.

BY JOHN A. JEFFRIES, M.D., BOSTON.

IN view of the recent article on typho-malaria in Boston, by Dr. Whittier, the following cases seem of interest. They all occurred in an area bounded by the water, Kneeland, Kingston, and Essex Streets. The first two cases are examples of quotidian and tertian malaria, and are given as the histories seem to suggest infection contracted in Boston. The rest of the cases all occurred in one family, two of whom had typhoid fever at the same time. Both the relapse of malaria and the typhoid seemed to be due to crowding in two sunless, dirty, badly drained and ventilated rooms.

CASE I. April 28, 1887. J. H., male, twenty-six years old, married; has always lived in Melrose until last winter, when he moved into his present lodgings. Always healthy; knew nothing of malaria. When first seen he complained of being seized with fever, vomiting, and pain in the abdomen, about six in the morning. Now in a profuse sweat; temperature in the axilla, 103.6°, pulse 120, respiration 20. All the viscera examined, and nothing abnormal found. Urine clear, light, profuse; no albumen. Temperature at 5 p. m., 99°; pulse 80.

April 29th. Had a fever early this morning; temperature at 11 A. M., 101°; at 5 p. m., 99°.

April 30th. Had a fever same as the last two days; temperature at 11 A. M., 102°. Still no physical signs. Quinine ordered at night.

No more chills occurred, and patient went to work in two days.

CASE II. September 12, 1887. D. C., male, twenty-four years old, married. Born and bred in Paris, went to New Orleans for a week, and then came to Boston six months ago; never had a fever or periodic disease. At the time of my visit patient seemed unstrung, and gave a history of being waked up early in the morning by a hard chill, followed by fever and sweating. No physical signs.

September 13th. Seems perfectly well.

September 14th. Had a chill again this morning, with fever and sweating; still sweating at time of visit. Ordered a full dose of quinine four hours before the time of the next attack. From this time on no chills occurred, but patient was poorly for ten days, with a febrile rise of temperature on the even dates.

CASE III. August 8, 1887. G. D., male, seven years old, pale and thin; old history of tertian malaria in Springfield, two years ago. Now suffering from mild diarrhoea. Prescribed camphorated tincture of opium and bismuth.

August 9th. No diarrhoea, but child the same.

August 10th. No diarrhoea, but child has taken to his bed, and mother gives history of a chill about 9 A. M. Physical examination showed head and chest normal; the liver to be felt at the edge of the ribs on the right side, and a half-inch below the ribs on the left side; spleen out to ends of ribs, tense, tender; bowels not tender, gurgling.

From this time on the child ran a regular course of alternate poor and bad days, vomiting, numerous ochre stools, bronchitis, and prostration being the constant symptoms, and chills on alternate days. On the seventeenth prostration was great, and much stimulants had to be given. Convalescence was slow, rose-spots were not seen. The treatment was confined to quinine, milk, raw eggs, and whiskey. Below is given a temperature chart, from which it will be seen that during the collapse the malaria changed from the even to the odd dates.

CASE IV. August 10th. F. D., male, sixteen months old, brother of Case III. Caught malaria, when four months old, in Springfield. Had a distinct chill and fever, no sweat noted, on the 9th, 11th, and 13th. Treatment, quinine.

Shortly after, while the boy was still sick, the mother came down with tertian chills, and had to take much quinine. Spleen enlarged.

Lastly, on the 10th of September, the father came down with a mild attack, like Case IV, of which I was unable to secure any satisfactory records.

The first two cases are reported as examples of pure malaria, occurring for the first time in men who had for at least six months been resident in Boston. The

third case is a very fair example of typho-malaria, or, as I prefer to call it, and reported to the Board of Health, typhoid and malaria. It will be noted that the malaria was a relapse of an old trouble, apparently induced by the same lack of sanitary conditions that caused the two cases of typhoid.

All my other cases of typhoid fever ran a regular course, showing no sudden changes from day to day.

PROGRESS IN THE CARE OF THE INSANE.

BY WALTER CHANNING, M.D.

PROVISION FOR THE INSANE.

THE year 1887 has shown further and important progress in correct methods of providing hospital or asylum accommodations for the insane.

The theory that almshouses can be so managed as to properly care for and treat insane persons, has been strenuously and persistently combated, and in time such an inadequate, not to say reprehensible means of provision must be wholly done away with.

Strong arguments in favor of placing the insane entirely in the care of the State have recently been advanced by the *American Journal of Insanity*. The *Journal* quotes the following, in its January number, from a letter of the Hon. Wm. P. Letchworth, President of the New York Board of State Charities:

"I believe there is no question but that State care is better than county care; and when the cost is not estimated, but arrived at by a separate system of accounting, is cheaper. Several counties have tested this, and found to their surprise that their insane cost them much more kept at home than if sent to Willard (a large asylum for the chronic insane). . . . The reason why State care is better lies in the fact that it is administered by uncompensated, non-partisan boards, whose members are employed for long terms. Boards of supervisors are constantly changing their membership, and the great advantage arising from cumulative experience is lost. Besides, under the county system, the care of the insane becomes, to a greater or less degree, a medium for the distribution of political patronage."

Dr. P. M. Wise, superintendent of the Willard Asylum, reiterates what he has often said before, that each year's experience proves that the county care of the insane is liable to relapse into a condition far below a proper standard, and the remedy is not always within reach.¹ Dr. Wise quotes Dr. Henry M. Hurd, of Michigan, who says: "The county system, as a whole, lacks definiteness of plan, and is haphazard and capricious, depending too much upon local public sentiment and individual ideas of reform and economy."²

Taking the experience of nearly all observers of the last thirty years, it may be stated as a settled fact that State care for the insane is *safe*, county care hazardous, and generally *unsafe*, and any further steps taken in providing for the insane should be made clearly and systematically with this idea in view. Any exception, any departure from this plan, however attractive and easy at the moment, will be pretty sure to be attended by unfortunate consequences in the end.

¹ Annual Report, 1887.

² Colony System of Michigan.

The building of the last year has been done very much in accord with the above principle, for what I have called an *idea* should be more correctly called a *principle*. I have already alluded in the JOURNAL to the "Colony System of Michigan," which has been further developed at a trifling cost with complete success. New York has been very active in carrying out this principle, and if coming events cast shadows of any value before, we may soon expect to see her insane cared for in the ideal manner. To be sure the insane of the city of New York are far from being provided with adequate accommodations, and the "Willard exemption act" is still in force, but both these evils are being actively agitated, and the spirit in New York, as far as her insane is concerned, is so progressive that we cannot doubt that the proper remedy is sure to come.

The accommodations at the State Asylum at Poughkeepsie have already been considerably expanded, and it now has assumed the character of a "mixed" asylum, or one taking both the curable and incurable. The buildings for the latter class are on a different part of the farm from the buildings for the former class.

The most important undertaking in which New York is now engaged in her efforts to provide for her insane, is the contemplated erection of the new institution at Ogdensburg. The architect of this asylum, which is called the "St. Lawrence State Asylum for the Insane," lays down the following principles as necessary to the successful administration of an institution for the insane:³ 1. Buildings not more than two stories high; the first story for day-rooms, and the second for sleeping purposes. 2. Buildings for the feeble, helpless and disturbed to be only one story high; buildings for the latter being so situated as not to disturb other members of the asylum. 3. A sufficient number and variety of buildings to admit of ample classification, without adding to the cost of maintenance. 4. The general arrangements of the buildings to be such as to secure to the patients, as far as possible, the conditions of domestic life.

There are to be five groups of buildings, and fourteen detached cottages. The central and most prominent group comprises twenty-two separate buildings. Twelve of these, which are for the actual dwellings of the patients, are connected together and to the central building. The recent cases are to be cared for in six ward-buildings, three on each side of the administration, or central building. The day and sleeping accommodations are to be separate, and there are to be four associated dining-rooms.

A second group of buildings consists of one-story pavilions, and two two-story buildings, with two associated dining-rooms, all for the filthy and demented, two hundred in fifty being the supposed number. An assistant physician with his family would reside in this building.

A third group of seven buildings is for a physically stronger class of patients, and they are two stories high. One of the buildings is for a dining-hall for the entire number of two hundred and thirty-one patients. A physician would also reside in this group.

A fourth group is composed of three cottages, buildings of two stories, and a separate one-story building for a dining-hall, seventy-five feet apart. This group

would accommodate two hundred and five patients of the intermediate class.

A fifth group is composed of detached cottage buildings, accommodating from twenty to one hundred patients each, of the quiet class.

GENERAL PARALYSIS OF THE INSANE.

It is of great importance for the medical profession to have this form of cerebral disease brought forcibly to their attention, as it represents one of the forms of physical degeneration dependent on the mode of life of the nineteenth century. First described by a French writer about sixty years ago, it was seldom seen or recognized in this country until shortly before the civil war. During the war and immediately after it rapidly increased, and since the end of the war it has gone on becoming more and more common.

The general truth of these assertions is pretty well borne out by the statistics of the State Insane Asylum at Utica, New York,⁴ which has been carefully and accurately kept since the opening of the asylum. We find that in thirty-nine years 630 general paralytics have been admitted to the asylum, of whom 407 have died, or nearly sixty-six per cent., while the general mortality of the asylum from all causes during these years, taking the whole number treated, have not been more than 9.80 per cent., and have fallen as low as 3.66 per cent. For the year ending September 30, 1887, there were 61 deaths in the asylum, and of these 15, or nearly 25 per cent., and all males, were cases of general paralysis!

The number of females in the total number of 639 was only 69, but of these thirty-nine died. Up to the year 1869 only twelve females were admitted. Since this time, with only a slight rise, say from eight to ten per cent., in the number of patients admitted, 57 females have been admitted, or nearly five times as many in the years from 1869 to 1888 as in the years from 1849 to 1869.

In the year 1887, 27 general paralytics were admitted into the asylum, while in the five years from 1849 to 1854, inclusive, with proportionately larger general admissions, but 16 were admitted, three only being females.

SYPHILIS AND GENERAL PARALYSIS.

A discussion on this subject took place at the recent International Medical Congress in Washington, in the section for Psychological Medicine, which perhaps did not elicit much that was new, but old and familiar data were put together in an interesting manner.

Dr. George H. Savage, superintendent of the Bethlem Hospital for the Insane, in London, led in the discussion, a full and careful report of which may be found in the *American Journal of Insanity* for October, 1887, and January, 1888.

Dr. Savage described several groups of cases in which syphilis is related to general paralysis. In the first group were cases of syphilis of long standing followed by general paralysis with acute symptoms. He mentioned cases in which general paralysis had supervened after the syphilis had existed from seventeen to thirty years. It occurred rather suddenly, and went on quickly to a fatal termination. He thought there was no doubt about the syphilitic origin of these cases.

In the second group were cases which ran the course

³ Report to the Board of Managers, by M. J. G. Perry, *Am. Jour. Insanity*, Jan., 1888.

⁴ Annual Report for 1887.

of ordinary general paralysis in the ætiology of which syphilis is an undoubted factor, but which in no way modifies the symptoms of the disease.

In the third group were cases in which, after a well-marked history of primary syphilis, symptoms due to a local syphilitic nerve-lesion, such as paralysis of the muscles supplied by the third nerve, monoplegia, hemiplegia, simple aphasia, appear. These cases which come under anti-syphilitic treatment, and in some instances are apparently cured, later become weak-minded, and develop symptoms of general paralysis.

In the fourth group were cases starting in the spinal cord. Many writers assert, Dr. Savage said, that the larger number of cases of locomotor ataxy have some syphilitic history, and a very fair proportion of cases of general paralysis begin with locomotor ataxy. There are several forms. In some the ataxy develops first; in others the ataxy and the general paralysis develop about the same time.

Dr. Savage had seen only one case of general paralysis appear to get well, and he died of some obscure nervous disease under Dr. Ferriar. Probably this was a case of syphilitic general paralysis with a prolonged remission.

Dr. Langdon Down, of London, thought that nearly all cases of locomotor ataxy were of a syphilitic character.

Dr. Yellowlees, of Glasgow, made some very sensible remarks. He thought we should be very careful in our deductions as to the effect of syphilis in the history of the disease. "They unquestionably coincide in the same individual without the cerebral paralysis being at all perceptibly modified thereby." Cases beginning with spinal symptoms are probably of syphilitic origin. In cases of general paralysis occurring in patients with a history of constitutional syphilis, we have the disease modified to a greater or less extent by local paralysis, and by a greater tendency to local paralysis than in the ordinary cases, and that is the whole of the matter. "At least I don't know that our present knowledge gives us farther light than this gives us."

Dr. Nichols agreed to a certain extent to what Dr. Yellowlees had said, and added: "I have supposed that excessive venery, excessive intellectual labor, and loss of sleep were the most efficient causes of general paralysis of the insane. These causes, it seems to me, will produce this form of mental disease independently of syphilis. It has seemed, and does seem to me, that syphilis is not an essential cause of general paralysis of the insane."

HEREDITARY SYPHILIS AS A CAUSE OF IDIOCY AND IMBECILITY.

In connection with the discussion of syphilis as a cause of insanity, a paper by Dr. Fletcher Beach, of England, on this subject was read, its purport being to show that these forms of mental defect are rarely the consequence of inherited syphilis. Dr. Langdon Down, Dr. Beach said, did not find in more than two per cent. of his cases signs of inherited syphilis. Dr. Ireland was of the opinion that hereditary syphilis was not a frequent cause.

The disease leads more often to juvenile dementia about the time of puberty, then to idiocy or imbecility. "Of course constitutional syphilis can only lead to idiocy or imbecility by causing some disease of the skull, brain membrane, or arteries, or all of these

combined, and so affecting the nutrition of the brain, and though *a priori* one would think idiocy should be a frequent result, yet practically it is not so."

THE PARETIC COMPOSITE PHOTOGRAPH.

A ghastly, though perhaps not unprofitable example of the latest photographic "fad," the composite portrait, is found in a recent number of the *Journal of Nervous and Mental Diseases*.⁵ This consists of composite photographs of general paralysis and melancholia. The first one is made up from negatives of eight patients, three females and five males.

As the writer says, the percentage of females is higher than in the natural ratio of the two sexes in the disease. The cases are all in the second stage of the disease, and their individual portraits show the marked characteristics of general paralysis. The average duration of the disease at the time of photographing was, in the women, two and one-third years, and in the men one and three-fourth years.

The composite, according to the writer, and as far as one can judge from the picture given, seems to fairly represent the physiognomy of general paralysis. The eyes have the typical inexpressive and staring look; and the facial lines of expression have been gradually obliterated and smoothed out, giving the well-known appearance of easy-going complacency.

Though this number of cases is small it is still of some value, especially in so well-marked a disease as general paralysis, where a composite of fifty cases would not give a much more characteristic picture than one of ten. In other forms of mental disease a large number would be necessary to establish anything like a type, but such work is in the right direction, and will aid in establishing what we so much need—clinical pictures of the various kinds of insanity.

PERSISTENT AND FIXED IDEAS.

Dr. Edward Cowles has recently published a paper on this subject⁶ consisting of the analysis of a case with prefatory remarks. The study of this case is worthy of special comment because it is done in the most painstaking, thorough and continuous manner inspired by the spirit of true scientific research. As far as my knowledge goes, it is the best study of a case of mental disease that has appeared of recent years in our American literature, and should serve as a model for others.

Modern psychiatry, Dr. Cowles says, has differentiated two great general groups of idiopathic mental disorder. The first group includes those that may happen to a healthy mind in a healthy brain, and are manifested in typical and regular forms and courses of mental phenomena. The other group contains those that occur in unstable minds correlative to constitutional brain defect, hereditary or acquired, and are manifested in irregular forms, in which the phenomena are made distinctive by being modified and varied in their order and degree from those in the first group.

To the first group may be applied the term "ordinary insanity," and to the second "paranoia."

The general relation of these physical and psychological elements may thus be stated in terms of function; as the stable mind is to the unstable one, so are the dis-

⁵ January, 1888. Composite Portraits of General Paresis and of Melancholia. By Wm. Noyes, M.D.

⁶ American Journal of Psychology for February, 1888.

orders, psychoses, incident to the former, to the degenerative processes in the latter, or so is ordinary insanity to paranoia.

The science of psycho-pathology deals directly with the central object itself; the mind is the man, and the conservation of mental integrity the aim. In the minute study of the psychical elements involved, the clinical student has in his field as important a branch of the new psychology as the pathologist or psycho-physicist.

There is a multitude of cases of the minor degree which, as far as they go, have all the essential characteristics of "fixed ideas," but in which the "idea" is not as fixed as to be always dominant; it can be resisted more or less successfully at will, in the milder cases, which are in a large majority. The ideas are simply insistent, and the term "insistent ideas" is here proposed as being more generic, and as including all forms, some of which became "imperative" and "fixed."

In the case reported, Dr. Cowles does not attempt a demonstration of the proposition he advances, though he thinks there is much in the case to sustain them.

The patient was a young woman twenty-eight years of age; the youngest of ten children, and without heredity. She was of more than ordinary intelligence, and of good sense, usually amiable and pleasing in manner. She was negligent of her dress, but showed to the ordinary observer no indication of mental weakness. To two of her physicians only did she reveal her morbid mental peculiarities.

From ten to twelve she had fears of harm and doubt as to whether simple acts were right, and she had to repeat some acts. At fourteen she was exhausted by a nearly fatal attack of typhoid fever, and menstruation began. She began again to repeat simple acts, as walking, dressing or undressing, and could not help it. Here was the beginning of a common form of fixed ideas. The idea that the act is wrong, with a vague fear that some harm will follow if it is not made right, and the necessity of repeating the act to make it right, is the starting-point in this case.

Among the friends of M., the patient, was one called C., beautiful and attractive, but the intellectual inferior of M. M., though very fond of C., became jealous of her, and finally thought she hated her, and thoughts of harmful things that might happen to her came into her mind. These feelings so far were only natural. But soon M. began to ask herself if she should not do violence to C. if she had an opportunity. This idea became mixed with the repetition of her acts; there was a feeling of vague fear if she did not repeat them; then there came to be associated with the insistent idea a definite feeling of fear of harmful consequences to C. if the morbid impulse of the repetition were not obeyed; then for a time this fear was dispelled by compelling herself to repeat the special act a certain number of times, more or less on different occasions. This fear of injuring C. was harmonized with her so-called hatred of her, as it was not so much because of the pain of contemplating possible harm to C. as because of the suffering M. feared would be inflicted upon herself by her offended conscience, if any such harm as she thought of did happen to C.

The feeling that something would happen to C. became so fixed in the mind of M. that she became unable to read or hear or think of any painful thing,

fearing that it was about to happen to C. She found a way to allay her painful feelings by thinking of some person known to her other than C., whom she would mentally substitute for the latter, and whom she would set up in her mind the moment the morbid idea came, to be the recipient of the suggested harm. Then it became necessary to carry this plan further into detail; the substituted person had to be a person with many characteristics opposite to C.; for example, there had to be a difference in age, sometimes of sex, initials of name, color of eyes and hair, etc. Next it became necessary to have ready in mind a number of chosen persons, two or three or four of whom, as the case might be, must be thought of in a certain order.

It is impossible within the limits of this article to further follow the analysis of this case, which with great elaboration demonstrates the complicated yet logical connection of one set of ideas with another. Enough has been given to show the character of the mental operations which, as Dr. Cowles says, "were all more or less insistent or imperative, strictly according to the closeness of association of the ideas with the central and ruling one; and corresponding also to the degree of fixation of such methods of mentation by repetition, practice and habit. All these products of mental phenomena are explainable upon the basis of normal psychical law."

HEMORRHAGES AND FALSE MEMBRANES.

Dr. Joseph Wigglesworth has written an interesting and suggestive paper on hemorrhages and false membranes occurring in the subdural space.⁷

He comes to the following conclusions: (1) The morbid conditions described under the term *pachymeningitis interna hemorrhagica*, are not the result of inflammation at all, but are solely due to the effusion of blood beneath the dura mater, the hematoma thus formed becoming organized, and eventually converted into fibrinous membranes. (2) Such effusions of blood are especially liable to occur in the insane by reason of the loss of support sustained by the meningeal vessels on account of the convolitional atrophy which is so marked a concomitant of insanity, assisted as this condition so frequently is by transitory or more permanent congestions. (3) It is because these conditions are most perfectly fulfilled in general paralysis that hematomata are more often met with in this disease than in any other form of insanity. (4) Whilst subdural hemorrhage is by far the most frequently found in chronic cases of insanity, it is also met with in a small minority of acute cases, chiefly, if not solely, when the symptoms have been of a melancholic character; and in these cases the hemorrhage may introduce a complication which may eventually be the cause of the death of the patient. (5) Whilst in the great majority of cases traumatism may be confidently excluded, there seems reason for believing that, under favorable predisposing conditions a slight injury may start hemorrhage which will prove fatal.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOL- OGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

REGULAR meeting at 19 Boylston Place, Wednesday, February 8, 1888.

DR. ALBERT N. BLODGETT, Secretary of the Section, said: A matter of business which I would like to place in the hands of the Chairman is an address from the College of Physicians of Philadelphia. This pamphlet is addressed to the various medical societies of the country, and I presume that most of them have received a copy, in order that they may see what has been already done, and begging their coöperation and their moral support in the effort to increase the efficiency of the quarantine regulations of this country.

On motion of DR. BARNES, the matter was referred to a committee of three, consisting of Drs. H. T. Barnes, C. F. Folsom and S. H. Durgin.

DR. HENRY JACKSON then read a paper on

FIFTY CASES OF SCARLET FEVER.¹

DR. S. H. DURGIN said: The paper has been interesting to me. It shows that the rate of mortality in scarlet fever patients the past year has been rather large. That I find to be so in looking over the whole number of cases for the year 1887. While the percent of mortality to the total number of cases reported has usually run along about five or six or seven this year I find that the death-rate has been a little more than twelve per cent. The mortality for the last quarter of the year was very much greater than for any other part of the year 1887. I am pleased to hear the reader speak of the superadded condition in the throat. It sometimes bothers me to know what record I shall make when a case comes in with a history of having had scarlet fever eight or ten days, and diphtheria three or four days. There seems to me to be a difference of opinion among physicians as to whether this membrane shall be considered as a different disease, diphtheria, or whether it is a part of the severe type of the scarlet fever. Personally, I have preferred to regard it as a part of the severe type of the scarlet fever. I don't know that I am right; at any rate, I shall be glad to have the question settled for the sake of the records.

In looking over the records since 1850, it is very interesting to see the course of scarlet fever in Boston. There had been almost a continuous endemic condition down to 1877, and at that date I think the first efforts were made on the part of the authorities to stay the progress of this disease; and however feeble these attempts were at the time (and I know that they were not as radical as they should have been, and as I would like to see them), yet the means put forth at that time have either had a marked influence in suppressing the disease, or else there has been a most fortunate change in some other way. At any rate, the number of cases and number of deaths diminished from that time; for a few years I thought it might be a temporary holding up, but it is now eleven years since this break began, and there is a very satisfactory diminution in the number of cases of scarlet fever.

At that time we decided to exclude from the schools pupils coming from the houses infected with this contagious disease, and that has been done with more or less effect; that is to say, the greater number are shut out from the schools. I don't think that it is perfectly carried out, but it is to a large extent. The fumigation of houses after the removal of the patient after death or recovery has been quite persistently kept up; it seems to me that it is fair to assume that it has had a good effect.

I have looked over the records somewhat to see whether cases have recurred in houses where the fumigation has been made, and so far as I can draw conclusions from these records, I should say that the effect is most marked. One instance came to my notice this afternoon, where, in one of the streets in the South Cove, for five years previous to 1881, diphtheria and scarlet fever had been reported in this house, with several deaths. Cases had been reported repeatedly.

At that time it was taken in hand, and about two hundred pounds of sulphur were burned; and since then there has not been a case of scarlet fever or diphtheria reported in that house, although it is occupied by eight or ten families. This is only one of quite a large number of instances that were given me this afternoon in which it seems to me fair to conclude that the disinfectant has had a good result.

In regard to the treatment of scarlet fever officially, I should say that, as in the case of the other contagious diseases, isolation and disinfection were the two things that we must look to for preventing the spread of these diseases, and especially so in the case of scarlet fever. Isolation is very hard to obtain in this disease. We have very little hospital accommodation, and the trouble is, in sending these cases to the City Hospital, that they do not take the mothers with the children, and you might as well attempt to get a pound of meat from a living man without a drop of blood, as to get the babies into the Hospital without the mothers. You can't do it. In small-pox, that was the way we treated it. We took all that could go, and cleaned the house out. You must do that with scarlet fever, if you will isolate the cases. We cannot do that now, although I should like to see it done; and we are left with the palliative measures, disinfecting where we can, and isolating to the best of our ability, which is rather poorly done.

DR. ALBERT P. WEEKS said: We have had quite an epidemic of scarlet fever in Chelsea. I sent to the Board of Health this afternoon, and found that there had been reported 209 cases; but I don't imagine that that represents more than four-fifths of the cases that have actually existed. I should say that we had had, at least, 250 cases since the first of October. It existed there in the latter part of the spring and through the summer, but only in isolated cases; sometimes we would not see a case for four or five weeks. Out of that number I find that there have been twenty-five deaths. I am sorry to say that I think the majority of these were in homœopathic hands. Homœopathy is not so successful as it used to be in scarlet fever. I have had three cases outside of Chelsea. I find that in all I have had thirty cases since the first of October, and these have presented quite a variety for treatment.

I have had two deaths out of thirty cases. One died of convulsions, the first day of the disease. The

¹ See page 421 of the Journal.

little brother had the disease very mildly, and I cautioned the family to keep the other one, which was smaller, away from that one; but the father said he might as well have it, and it was one of the families that let them do what they please. He went into convulsions, had purging and vomiting, and lived about twenty-six or twenty-eight hours. The other death seemed due to the intensity of the fever. I never saw an eruption equal it. I could not take the temperature, the little thing was so restless, but it seemed to be very high indeed. It died on the fifth day. I found one anginous case, a very bad throat, discharging that yellowish fluid from the nose which accompanies diphtheria, with no thick patches on the throat, but more like follicular deposit, with no sign of eruption elsewhere. Had it not been that the little sister came down about the same time with the scarlet fever, I should have questioned whether it was not nasal diphtheria really, although I got no sign of membrane in the nares. I have had one case of acute Bright's with anasarca, one case of abscess of the glands, the submaxillary, and one of hæmo globinuria.

Most of the cases have been comparatively light. The prodromic period has been of the usual shortness, manifesting little abnormality; vomiting has not been troublesome, except in a very few cases. Diarrhœa existed in one or two cases. My treatment has been mild febrifuge treatment: sponging, anointing with sweet oil, and bromides, if there was headache. The after-treatment in most of the cases I left to nature. I found but few of them who showed any signs of albuminuria when they have been kept carefully in, and upon a careful diet. I don't give my patients a very heavy diet; I keep them rather upon milk and starchy fluids than let them have such diet as would work upon the kidneys. It seems that our mortality there has been about one in ten, taking cases as they have gone. I have lost two out of thirty.

DR. DURGIN: There came to my notice to-day, in the *London Lancet*, a statement in regard to the contagious period of scarlet fever. They regarded the period of contagiousness as running from the first appearance, to the time when all *roughness of the heel and ankle* had disappeared, and they found that time to be for the five years, 1878 to 1882, inclusive, as follows: In one year the average number of days was 54, two years it was 70, and one year it was 74 days. It seems to me that this is a very much longer contagious period than we have been accustomed to think here in Boston. It seems to me only a few years ago when four weeks was regarded as the average time in which to regard the patient as in condition to give the disease.

This is certainly a very interesting question. If we are discharging patients and letting them come into contact with others, or allowing them to leave the hospital while they are in a condition to give off the disease, it certainly seems to me wrong. I hope that some discussion of this question will arise, and I would like to get the opinion of different physicians who have observed this condition. In regard to the roughness of the heel and ankle, it is something that I have never looked for, but in a general way, when asked in regard to the contagious period, I have been in the habit of telling people that when the skin was smooth they were free from contagion.

DR. C. F. FOLSON: I was interested in what Dr. Durgin said, and I have no doubt the work of the

Board has been efficient in diminishing the amount of scarlet fever. Some little while ago, I prepared a thirty years' chart of all the prevalent diseases in Massachusetts, and though I have not referred to it for many weeks, I think I am correct in saying that the diminution which was noticeable in Boston in the last ten or twelve years has been the same throughout the State and therefore not wholly or perhaps chiefly due to sanitary measures.

There has been another curious fact, namely, that since the very great prevalence of diphtheria there has not been in the State or in any part of the State any severe epidemic of scarlet fever to the same extent that it had prevailed in several epidemics before that. It is quite a curious fact to notice that in several towns of the State the two diseases, diphtheria and scarlet fever, have had to a certain extent an alternate prevalence; that is to say, in the years that diphtheria was quite prevalent scarlet fever was much less prevalent, and *vice versa*.

If I remember, and if I am wrong perhaps Dr. Durgin can correct me, the epidemic of diphtheria, which may now be considered endemic, began in 1873, commencing in the northwestern part of the State, and my impression is that it was two or three years before it got to Boston in full force; and since that time there has been a very striking diminution in scarlet fever throughout the State. That is particularly noticeable if one looks at the chart, the diphtheria line going up and the scarlet fever down.

I am very much struck at the condition of the public intelligence in regard to the control of the contagious diseases—that it is so far behind what it is in other places. If you go to the cities of England or Scotland and tell them what is not done in the cities here, they will shrug their shoulders and say: "Is it possible?" For instance, I think I am right in saying that there is not a single city in the United States which has a fever hospital in the proper sense, with the exception of the so-called pest-houses or small-pox hospitals. The law requires, in England, that every town of any considerable size shall have a separate hospital for the isolation and control of all contagious diseases, scarlet fever, diphtheria, etc. In a great many of them the measures for control are very complete.

I think perhaps, on the whole, the city of Glasgow is more thoroughly provided with the means of controlling these diseases than any other of the cities at the present time, and it might be worth while to say what they are doing, to see how far behind we are. In the first place, Glasgow is a city with a population twenty-five per cent. greater than that of Boston—a little more than five hundred thousand. Their hospital for contagious diseases consists of thirteen entirely separate buildings, on a lot of 31½ acres—three-fourths the size of Boston Common. It is in the suburbs of the city, on the banks of the Clyde. In one portion of the thirty-one acres there is a separate enclosure for small-pox. If I remember, there are three buildings there. The other ten buildings are for typhoid, scarlet fever, etc.; that is, more than one building for the separate diseases. These are entirely separated from the other hospitals, and the contagious diseases separated from each other.

In regard to the point of isolating small children, the city has provided small buildings into which you can put an entire family, and isolate them as long as

you choose. These buildings are pleasantly situated and very convenient, and it is customary to take an entire family and keep them there at the expense of the city.

The city controls altogether the sale of second-hand clothing, which is subjected to disinfection, and linens are washed under sanitary supervision. The isolation, of course, is what one would suppose it would be. Beside that, they have a number of public laundries where women can go and wash their clothes at a cheap rate, to discourage their washing them in tenement houses.

They say that they have diminished contagious diseases enormously, but I think it would be perfectly wild, in the present state of public information, to hope to get any of these sanitary measures carried out in our American cities. It seems strange, too, for public opinion seems in general to be in advance of those cities.

DR. VICKERY: I would like to ask, Mr. Chairman, in regard to the treatment of these cases, about the skin. Is anything done to lessen contagiousness?

DR. JACKSON: I generally told them to anoint the child with oil, and then wash it with water. No disinfection, as was spoken of in the journals last summer, was undertaken.

DR. VICKERY: I asked the question to bring out the opinion of the gentlemen present as to the possibility of rendering the scales that come off innocuous.

DR. MASON: In regard to that point, I can only say that we see a good many bad cases of scarlet fever at the City Hospital, and I think it is customary usually to have the skin rubbed with some carbolized ointment. How far that is beneficial in removing the contagion, I don't know. I should like to ask the reader if he noticed in regard to the period of invasion of these cases, if it was ever prolonged beyond a few days.

DR. JACKSON: In one case it was eleven days.

DR. MASON: After the first symptoms?

DR. JACKSON: After the exposure.

DR. MASON: I mean the period of invasion, after the first symptoms are shown. I don't mean the period of incubation.

DR. JACKSON: It was always short.

DR. MASON: I ask because a year or two ago I was called to see a teething child, who had severe symptoms suggesting meningitis; vomiting, stupor, fever, which lasted a week — so long that the idea of scarlet fever was given up. On the eighth day the rash appeared on the chest, legs, and arms, and afterward desquamation followed. I think that is probably a very unusual time. I found that a few cases were recorded where the rash did not appear for a week or more, but this was rare.

DR. BARNES: Dr. Jackson speaks of his being unable to take any precautions. A member of this Society told me a few days since of a case where he was in attendance, and six days later his own child, three or four years old, was taken sick with the disease, and he considered that he brought it to the child.

DR. JACKSON: I don't, of course, pretend to say that scarlet fever is not contagious, or that it could not be carried. I had charge of this district, where I had a great number of cases to see daily. There were generally seven new cases in a day; that is, two hundred new cases per month, and it was impossible for me, in going my rounds, to change my clothes.

After seeing these patients, I changed my clothes before seeing private patients. It was a curious fact to me that I did not carry the disease. And yet, we ought to be as careful as possible.

DR. WEEKS: I meant to speak of that point myself. I have watched it in my own practice very carefully, and I never but once thought I carried the disease. That was to my own child, nine months old. That was in a case that was close to my own house, and which I visited late in the evening. I assisted in the care of the child: I think my oldest boy contracted the disease in that way. I have a little fellow five years and a half old, and since his birth I have probably attended seventy-five or a hundred cases, and I never carried the disease to him. Sometimes I have had him out riding with me and been called to new cases, and have found that I had cases of scarlet fever, and I have had to take him home with me. I don't think the contagion is so easily carried as many people imagine. Sometimes I have been suddenly called to a child after visiting them, so that but little time would elapse between the time of the visits, but I have never seen anything come of it. I take the precaution to make these visits, when I can, in such a way as to protect other children. After making a visit to them I perhaps ride out as far as I am going, and work my way back, or else leave them to the last of the forenoon if I can, and then not see any patients again until after office hours. By so doing I am very sure that I have never carried the disease at all.

DR. SIERMAN: It has usually been considered that measles may be contagious before the rash appears, but that with scarlet fever there is not so much danger. But this is not always the case. Two weeks ago a child four years old entered the Home of which I have charge. This was Thursday, January 26th. He appeared well until Sunday, when he was taken with vomiting. The matron found the temperature 104½. She promptly isolated him. The temperature the first time was taken in the rectum. That night in the axilla the temperature was found to be normal. So she thought the child was well. But the next morning she found it was 104°, and the child began to complain of sore-throat. As she could not summon me readily, and thought that it might be scarlet fever, she promptly sent the child away from the Home. There was no other cases in the Home until the next Sunday. Before the nurse sent the child away she observed that there was no rash on the body. The rash appeared the next day.

On the Sunday, a week later, a seamstress, a young girl of twenty-three, was taken sick with sore throat and fever, and developed a rash upon the second day. The seamstress had only seen the child for a period of twenty minutes when she sat in the room by the bedside and watched him while the nurse went out to get a change of air. That was the only exposure, so far as can be found out, that she had had to the case.

DR. DUGGIN: I saw in 1868 a very singular case which illustrates possibly the extreme contagious character of scarlet fever. This experience was upon Deer Island. It was in the house of a family who lived alone, a father, mother and a little boy, about six years old. There was not a case of scarlet fever on the Island, either in the Institutions or in private houses, and had not been for many months. The father of this family left the Island and went into the

town of Winthrop, a distance of one and a half or two miles, in the winter, when the wind was pretty brisk, and visited a family where there was a case of scarlet fever. He sat in the house not over twenty or thirty minutes. The journey home required at least three-quarters of an hour. His boy fell sick with scarlet fever in about a week. It seemed to me that this was an extreme case, and therefore I made careful inquiry as to letters or packages, or anything that might possibly have brought scarlet fever, but I was able to eliminate everything except this visit of the father to this family.

DR. WEEKS: The first case of scarlet fever I ever saw was in a village. There had been no cases there for several years, and there were none in the neighborhood round about. The family had no communication with the outside world that would bring it there, and it was a mystery to the physicians there where the thing came from. But from that we had an epidemic running through the village. It breaks out sometimes very mysteriously.

I have two children, one seven and a half, and one nine months. I can find no traces of anything which communicated it to them. They have not been out of the house, they have received no packages, no one has been there, but they came down at the same time. And yet at other times great exposure does not communicate the disease.

DR. FOLSON: Quite a number of cases like that reported by Dr. Durgin have been reported to the State Board of Health, but in every case the individual who was supposed to be the carrier sat in a room which was a close one, and then on going out buttoned a heavy overcoat tightly around him, and if there was anything on his clothing the wind through which he passed would be of no avail.

In regard to Dr. Weeks's case, I suppose there are very few of the profession at the present day who would explain the case by saying that it arose without contagion. I suppose we would say that it would be like a case of small-pox occurring under similar circumstances, that it was a case where we are unable to find the source of the contagion.

DR. MASON: I would like to ask Dr. Durgin how long children convalescent from scarlet fever, should be excluded from the schools?

DR. DURGIN: The State law, made about two years ago, requires that the child shall be detained from the school two weeks after recovery. Of course, this matter of recovery is something very indefinite, and what the law exactly contemplates I don't know. I know that a great many children go out who are capable of carrying scarlet fever to others. When we send about for disinfecting purposes, we find children going about and others coming in to play with them while the desquamation is still going on, and some children are certified and go back to school before they are free from danger. I really feel that there is not that substantial unanimity of opinion in the profession in regard to how long the child should be kept away from others when it has scarlet fever. I am afraid a great deal of disease is spread in that way, by allowing contact too soon.

DR. MASON: In observing cases, chiefly at the City Hospital, I have noticed that the exfoliation, which is usually finished in three or four weeks, sometimes continues three months, the skin exfoliating several times. But I have never seen any

proof that this late exfoliation was capable of transmitting the disease — that is, no positive proof — and so far as my own practice goes, I have generally dismissed children at the end of four or five or six weeks, thinking that the late desquamation is probably not capable of carrying contagion. I have never known any trouble to arise from it, nor have I ever seen cases in families where I have gone after treating scarlet fever patients.

DR. DURGIN: I think that this matter of the scales being the sole or the principal cause of contagion is something that is entirely unproved. In the case of my own children it was eleven weeks before they ceased desquamating.

DR. MASON: In the report of the Glasgow Hospital I find that the average duration of time which the scarlet fever patients spend was eight weeks. I should say that this was unusually long.

I don't believe that the patients who have freely desquamated once, are capable of transmitting the disease except in the rarest instances of extreme susceptibility on the part of the person to whom it might be carried. But this is a doubtful point, as is also the question of diphtheritic complication which Dr. Jackson has referred to. We see at the Hospital many cases of pseudo-membranous inflammation, and this is considered by some as anatomically the same inflammation as diphtheria; whether it is or not, we do not know, but so far as my observation has gone clinically it is the same disease. Patients die, and I think I have seen them die from complication of the larynx, as Dr. Jackson considered in one case. I would like to ask the reader also if he made any observation about the length of time during which contagion might remain with the individual.

DR. JACKSON: I did not; they went from my care.

DR. A. N. BLODGETT said: There is one source of infection which I would like to mention which is apparent, but which is not sufficiently appreciated. I believe; and that is the danger arising from the dissemination of books from the Public Library. I have frequently seen these books in the families to which I have been called, which were the means of entertainment for the entire family, and which were tumbled about and subjected to every possible use and abuse, and returned without any degree of disinfection to the library. I have seen them taken from the library so offensive to sight and smell that they might in my opinion be capable of communicating any sort of disease to which they might have been exposed. I believe that this is a serious danger to many people, and particularly to the poorer class of people who are not able to buy books.

I believe this subject was at one time broached, and the necessity of disinfection has certainly been urged more than once, but I have never heard of any steps being taken in that direction. I see no reason why a book may not be the means of communicating disease when abused as the public library books are. They are public property, and are not considered as the books of the family would be.

Going from hand to hand and from family to family as some of them do, they seem to have every possible facility offered them for taking up the germs of scarlet fever or any other disease, and would be perhaps a very efficient means of spreading a disease which was communicable by germs.

Recent Literature.

Cyclopædia of Obstetrics and Gynecology. Vol. V: Gynecological Diagnosis; General Gynecological Therapeutics, by R. Chrobak, Vienna; Electricity in Gynecology and Obstetrics, by E. H. Grandin, M.D., New York. Vol. VII: A Handbook of General and Operative Gynecology, by Dr. A. Hegar, Freiburg, and Dr. R. Kaltenbach, Giessen; second volume. Vol. VIII: Diseases of the Ovaries, by Dr. R. Olshausen, Halle. Vol. IX: Diseases of the Female Mammary Glands, by Th. Billroth, Vienna; New Growths of the Uterus, by A. Gussierow, Berlin. Vol. XI: Sterility; Developmental Anomalies of the Uterus, by P. Müller, Bern; The Menopause, by E. Börner, Graz. Vol. XII: Diseases of the Tubes, Ligaments, Pelvic Peritoneum, and Pelvic Cellular Tissue; Extra-Uterine Pregnancy, by L. Bandl, Prague; Diseases of the External Female Genitals; Lacerations of the Perineum, by P. Zweifel, Erlangen. Edited by E. H. GRANDIN, M.D. New York: Wm. Wood & Company. 1887.

These six volumes complete the gynecological portion of the series, Vols. VI and X of which have been noticed some months ago. As will be seen from the subjects treated, they constitute a very complete treatise on this important branch of medicine. The authors are Germans, and we get mainly German ideas, but this has its advantages. While we may, perhaps, be prone to arrogate to ourselves a preëminence in this department, we cannot claim any such superiority as would warrant our neglecting what has been done by others. The Germans, especially in operative gynecology, can teach us many things, and this series is of value in that it gives to us in a cheap and readable form a great deal that is of distinct value. The authors are men of reputation and large experience, whose opinion in gynecological matters will be read with great interest. The publishers are to be congratulated on placing within the reach of the profession so much that is of value at so reasonable a price.

Hand-Book of General Therapeutics. ZIEMSEN, Vol. VII. Therapeutics of Circulatory Derangement. By PROF. M. Y. OERTEL. Translated by Edward J. Edwards, M.D., Lond., etc. New York: William Wood & Co., 1887, pp. xii, 271.

In our Report on Progress in Thoracic Disease,¹ will be found a critical notice of the above work, written before the appearance of the English translation. To that notice we beg to refer our curious readers. Here we will only add that the scope of the book is limited, dealing in great detail and ability chiefly with one class of circulatory disease, more common in Germany than in this country, and perhaps in Munich than elsewhere in Germany. The prime causative conditions are sedentary habits and the consumption of large quantities of fluid.

Diseases of the Chest. By JAMES R. LEAMING, M.D. New York: E. B. Treat. 1887, pp. 294.

This volume is composed of papers published in Medical Journals and Society Transactions at various times during the last twenty odd years.

Dr. Leaming was the first in this country, as far as we know, to insist upon the frequency of the pleural

origin of râles. Walshe had already pointed out that "moist sounds, rœchoid in properties, are producible whenever adventitious tissue within the pleura is infiltrated with serosity, and the movements of the chest continue free."² Clinical study, post-mortem examinations, and the physiological fact of the existence of residual air, which Leeming holds must prevent air currents synchronous with inspiration and expiration in the lungs themselves as distinguished from the bronchi — these considerations have gradually led the author to believe that all the fine râles as well as most of the coarse are inter-pleural, not intra-pulmonary. Thus the crepitant râle of pneumonia, the subcrepitant râle of pulmonary œdema or capillary bronchitis, arise within the pleura and are not heard unless the pleura is involved. "The signs of bronchitis of greatest diagnostic importance are not râles, but raised temperature, quickened pulse, with harsh and sibilant respiration," etc.

We cannot but think that Dr. Leeming goes too far in this direction, at the same time that we most cordially agree with him that moist râles both large and small originate in the pleura far more commonly than is ordinarily believed by the profession.

The râles of the asthmatic paroxysm are certainly not inter-pleural, nor are those in bronchitis which, as Fraser has so well shown, disappear immediately after a dose of a nitrite.

Dr. Leeming is a believer in the sedative action of a large dose of calomel — 20 to 60 grains, and having the courage of his convictions, took his own remedy when attacked by pneumonia of the left lower lobe, (p. 129).

We have read Dr. Leeming's book carefully and with much interest and profit. It would be well if all writers were so honest and so thoughtful. It is a matter for regret that more care was not exercised in some details of the writing or the proof-reading. We find in different places "bronchi," "bronchæ," "bronchiæ," "bronchia," "bronchii;" also "œdema," "atheramatus" — but we will not multiply examples. What an "esoric" ease we are at a loss to make out.

In a foot-note, page 26, it is stated that the presence of muscular fibre in the alveolar walls has been established. We cannot help thinking that Dr. Leeming is here in error. The paper and print are in no respect models.

F. C. S.

A Manual of the Physical Diagnosis of Thoracic Diseases. By E. DARWIN HUDSON, JR., A.M., M.D., etc. New York: William Wood & Co., 1887, pp. 146.

This is in fact though not in name the second edition of the manual published by the author in 1885 and noticed somewhat critically in these columns.² It has been much enlarged, modified in some respects improved, and profusely illustrated with original and borrowed cuts. Some of the former are pretty archaic; we fail to see the utility of inserting cuts of such instruments as stethoscopes, percussion hammers, and plessimeters.

We felt more strongly even than we stated that the first edition was not worthy of the author, and the second edition is, in our opinion, far inferior to the manual of Flint and by no means the equal of that by Loomis.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, APRIL 26, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE MORTALITY IN NEW YORK AND LONDON
COMPARED.

By direction of the Board of Health, Dr. R. S. Tracey, Registrar of Records of Vital Statistics, has prepared an elaborate report on the principal causes of mortality in the city of New York, particularly as compared with those in London. He commences by saying: "It is often said that New York ought to be the healthiest city in the world. As a matter of fact, London is, the annual death-rate of London being about 20 in 1,000, and that of New York 26 in 1,000."

The tables presented show the result of an attempt to find out whether the excess of mortality in New York is due to any particular diseases, and, if so, what they are, and whether the mortality from such diseases has diminished since the organization of the Health Department. The first table shows an excess of deaths in New York over London in certain diseases, in 1886, as follows: Small-pox, 65; scarlatina, 380; diphtheria, 4,129; croup, 2,261; typhus fever, 27; typhoid fever, 319; cerebro-spinal meningitis, 639; puerperal diseases, 5,942; malarial fevers, 1,109; diarrhoeal diseases, 5,942; erysipelas, 150; alcoholism, 250; phthisis, 7,383; pneumonia, 5,928; tabes mesenterica, 322; meningitis, 1,058; tubercular meningitis, 943; sunstroke, 121 (none in London); cirrhosis of the liver and hepatitis, 405; Bright's nephritis, 4,955; cyanosis and atelectasis pulmonum, 594; suicide, 246; premature births, 195; drowning, 241; violence, 1,362. The diseases in which there was an excess of deaths in London over New York were as follows: Measles, 160; whooping-cough, 1,214; rheumatism and gout, 146; cancer 439; bronchitis, 6,308; disease of the heart, 236; aneurism, 6; convulsions (?) 886; apoplexy, 19; diseases of the brain and nervous system, 446. For the purpose of comparison in the tables, the number of deaths in New York was increased in the same proportion that the population of London bears to that of New York; the population of London being given as 4,149,533, and that of New York as 1,439,037.

The next table gives the figures for the same diseases in 1880, the last census year, and in reference to the two, Dr. Tracey says: "It will be noticed that in both of these tables the diseases or groups of diseases in which there is a very marked excess of mortality in New York are the following: Diphtheria and croup (taken together), diarrhoeal diseases, phthisis and Bright's disease with nephritis (acute and chronic Bright's)." . . . Later he goes on to say: "As these two years might be exceptional, a table was prepared which shows the average annual number of deaths in each city for twenty years, namely, from 1867 to 1886, inclusive. . . . By that table it will be seen that the same rule holds good, namely, that the excess of mortality in New York is mainly due to diphtheria and croup, diarrhoeal diseases, phthisis, and diseases of the kidney. In all these tables there appears, besides the great excess of deaths from the above named diseases, a great excess from bronchitis in London, and from pneumonia in New York. They nearly balance each other, however, and the difference is probably due to the classification of broncho-pneumonia as bronchitis in London, while it is classified as pneumonia in New York."

A number of other tables having been given to test the truth of the foregoing statements, he finds that when the four causes referred to are eliminated from the mortality list of both cities, the death-rate from almost all other causes is almost the same. He then continues as follows: "These tables fairly demonstrate that the excess of mortality in New York, as compared with London, is due to diphtheria and croup, diarrhoeal diseases, phthisis, and kidney diseases, and the increase or decrease of deaths from these causes from year to year will indicate in some degree improvement or deterioration in the sanitary condition of the city." Next follows a table showing the average annual number of deaths from the diseases under consideration from 1868 to 1877, and from 1878 to 1887, inclusive, each period including a usually fatal year; namely, 1872 and 1881. "It will be noticed," Dr. Tracey says, "that the death-rate from diarrhoeal diseases and phthisis (diseases peculiarly sensitive to sanitary surroundings) has diminished appreciably, while that from diphtheria and croup and from kidney diseases has increased."

The conclusions arrived at are as follows: (1) That the excess of mortality in New York, as compared with that of London, is due chiefly to diphtheria and croup, diarrhoeal diseases, phthisis, and kidney disease. (2) That if the death-rate from these diseases were the same in New York and London, the mortality from all other causes remaining as at present in both cities, the general death rate in the two cities would be almost precisely the same. (3) That the overcrowding in New York (16.37 persons to a dwelling in 1880, as compared with 7.8 in London) and the trying climatic conditions render it very improbable that the death-rate of the city (New York) can ever be reduced as low as that of London.

STERNBERG ON YELLOW FEVER INOCULATION.

"THE question of etiology of yellow fever still remains unsettled; the claims of Freire of Brazil and Carmona of Mexico, with regard to the discovery of the yellow fever germ are without foundation; their statements and statistics of protective inoculation for this disease have no scientific value." These are the conclusions that Dr. George M. Sternberg has reached after personal investigation of the results of protective inoculation in yellow fever. Being commissioned by the President of the United States under a special act of Congress, passed about a year ago, he proceeded to Rio de Janeiro and Vera Cruz and his results will be detailed in his report to the United States Government. As the official report may be considerably delayed, Dr. Sternberg being about to go to Havana for the purpose of completing his investigations, he consented to present on the 21st inst. to the College of Physicians, of Philadelphia, the results thus far attained.

The technique of both Freire and Carmona was found to be very defective, both microscopical and bacteriological, proper staining and cultures not having been performed, nor were proper precautions taken to protect the specimens of blood, etc., from contamination with ordinary bacterial forms. In fact, the organism that Freire considers pathogenic and specific, Sternberg declares to be an ordinary form, probably *staphylococcus albus*. The organism found by Lacerda, confirmed by Babes, was a diplococcus Sternberg found in the kidneys and other organs in two out of nine cases, or in just about the proportion that the former observer had reported; as this organism is not constant, and was absent in some cases exhibiting otherwise well-marked characteristics of yellow fever, its causative action cannot as yet be accepted. Dr. Sternberg found, in one instance, a peculiar short bacillus in the glomeruli of the kidney, but as he had not succeeded in meeting with it again, he hesitated before assigning to it any special rôle in causing the disease.

The statistics of yellow fever inoculation upon examination were also found not to bear criticism and in fact, were generally discredited by the other physicians, members of the Academy of Medicine in Rio.

The question of the etiology of yellow fever therefore remains where it was left after the study of Sternberg and Guitierrez who were sent to Havana to investigate this interesting question by the National Board of Health in 1879.

It is hoped that the opportunities of pathological investigation which will be afforded Dr. Sternberg in Havana may enable him to shed more light upon the nature of the disease than he has yet done. By his recent investigations he has won the thanks of his fellow members of the profession, has rendered great service to his country and fully justified the election of the President of a commissioner to investigate the extravagant claims of Carmona and Freire.

REGULATING THE PURCHASE AND SALE OF POISONS.

THE Governor of Massachusetts by his approval, upon the 10th inst., of the Act passed by the present Legislature to regulate the sale and purchase of poisons, has secured for the public an important safeguard in regard to offences against the public health. Under previous legislation, only the sale of four poisons, arsenic, strychnine, corrosive sublimate, and prussic acid, had been in any degree guarded. Now, at least, thirty more preparations have been added to the former meagre list, and the sale of all those likely to be used with either criminal intent or culpable carelessness are surrounded with proper restrictions. These are such as will impose no undue restriction upon trade, but will tend largely to prevent accidents, and, in case of wrong-doing, to greatly aid in the discovery of the criminal.

The statute, however, furnishes another curious example of the frequent imperfection of such efforts, for with all the detailed requirements of registration of the name and address of the buyer, and the labelling of the sample in red with that of the seller, with the words poison and a recognized antidote, nothing at all is said in regard to the name of the poison itself being given thereon. This, of course, is the most important item of all these, which should be given upon the label, and its omission must, of course, have been an oversight.

The State Pharmaceutical Association, it is understood, has already taken action to conform to the requirements of the new law, and has commissioned one of its most able and active members to cause printed sheets of labels to be prepared, which will, in all particulars fulfil the new requirements.

MEDICAL NOTES.

— Dr. Freund's joke at the banquet given by Professor Kussmaul on his leaving Strasburg for Heidelberg has attracted considerable attention, perhaps from the fact that it has generally had to be explained to those whose classic lore had grown a little rusty. The speaker said that the guest of the evening was evidently no other than Oribasius, the body physician to the Emperor Julian, the Apostate, in the fourth century. Kussmaul is the exact philological equivalent for Oribasius. Whether the name in either case represented any osculatory proclivities on the part of the owner is not stated.

— "A case is reported in foreign journals," says the *Pharmaceutical Era*, "of explosion of a bottle of amyl nitrite which had remained a long time undisturbed in the store. It is not the first time an accident of this character has been reported, although, as a rule, explosions have followed attempts to remove a stopper which has become fixed in its seat. The real cause of these explosions does not appear, however, to have been generally recognized. They are due, no doubt, to accumulations of oxygen gas or possibly of

nitric oxide formed by spontaneous decomposition of the nitrite, and the ordinary precaution of storing the article in a cool, dark place is not sufficient, since the decomposition seems to take place even in the dark and at low temperatures. The fluid should, therefore, be kept in small bottles, and these should be occasionally opened, to permit the escape of accumulated gas.

— We learn from a foreign contemporary that in Paris thousands of women are cutting short their careers by the use of morphine. Morphine discs are dissolved in a small bottle of water, and this is placed in a case which includes a tiny syringe. The whole apparatus is of a miniature description, and can be conveniently carried inside the smallest muff. The vice has become so fashionable that women actually fill their syringes before starting for the theatre, and thus have the means at their disposal, any moment, of injecting themselves with the drug while lounging in the fauteuils or in their boxes.

— M. M. Caul and Y. Cowley have succeeded in determining the influence exercised by the process of roasting upon the proportion of caffeine contained in different kinds of coffee. Dry coffee contains from 1.1 to 1.18% of caffeine. If the roasting is effected at a moderate heat the loss of caffeine is trifling, but if it be, on the contrary, carried to a high temperature, the quantity of caffeine does not amount to more than 0.36%.

— A citizen of Stratford, in Avon, England, has recovered \$5,000 from the corporation of the town as damages for a nuisance caused by the defendants' sewage farm which is near his dwelling. The corporation admitted that a nuisance had existed. An injunction was granted by the court, to be suspended for a year, to allow the defendant corporation to put some remedial process in operation.

— A grim jest-book might be compiled from the prescriptions filed away in the shops of druggists, many of them reposing in austere loneliness under a disguise of execrable hand-writing. The following has been rescued from an obscure pigeon-hole by a Chicago paper, and is a relic of the pioneer doctors of fifty years ago: "A Recipe for Arnulda Purdy's Lung Complaint.—Take of the bark of wild Cherry, Sasparilla, Sycamore, yellow poplar, Dogwood and black oak, a Double handfull of each; take of Sasa-parilla Root and Spignard one handfull of each; to which add three Gallons of water. Boil it Down to one; strain it and add one quart of Good french Brandy and one quart of Honey, of which take about one Gill three times a day. This was tryed by Jonathan Douglas when he Could not Set up and has Cured Several others. N. B.—If She Canot take agreeable to Directions Take what She Can."

— Advice from Paris under date of April 6th, report that at its last sitting, the French Academy of Medicine concluded its labors on the "Public Means for Preventing the Spread of Syphilis." That body unanimously approved that portion of the report of its

Commission calling for the total abolition of disciplinary measures against the infected, the adoption of the best means of stamping out clandestine prostitution by warning young soldiers against its attendant dangers, and by combining the efforts of the civil authorities with those of the Army medical officers, with a view to the suppression of such dangers both in towns and in proximity to camps. Finally, the Academy adopted the following resolution in respect to the Navy: "Crews should be subjected to sanitary inspection prior to the ship putting into port; men found to be infected on inspection after a voyage of sufficient length, should not be allowed to land; suspected houses, and persons leading a debauched life in naval ports or ports of call, to be kept under medical surveillance; and the municipal authorities of such ports should be required to keep all persons suffering from disease in hospitals until thoroughly cured of all infectious symptoms." The discussion closed, M. Herard, President, congratulated the Academy for having initiated the agitation on this important question; agitation which is likely to result beneficially for the public health, and which has aroused the attention of the public powers, and thereby paved the way for such reforms as may be deemed necessary.

— The same protests that have been made against water-gas in Boston and elsewhere are now needed, and, we are glad to notice, are being made in Philadelphia. On the recommendation of a committee consisting of Drs. H. C. Wood, T. G. Wormley, J. W. Holland, H. Jayne, I. Norris, Jr., and H. Leffmann, the College of Physicians of Philadelphia adopted a resolution opposing the use of any illuminating gas containing more than ten per cent. of carbon monoxide. The basis of the objection is the danger of poisoning from this strongly narcotic gas. The resolution was adopted in view of the proposal to supply the city with a considerable quantity of so-called water-gas, made by the action of steam on highly-heated coal. Carbon monoxide forms about forty-five per cent. of this gas. The many fatalities which have resulted from this insidious agent cannot be too strongly or too often referred to, in order to protect the public against this peril.

— Dr. Wilks, who, nearly twenty years ago, directed attention to the fact that a transverse furrow appeared on the nails of the hand after a serious illness, again brought the subject before the London Pathological Society at its meeting on March 20th, and related a remarkable case, in which the furrow was produced in a gentleman in robust health by three days' seasickness. Mr. W. W. Wagstaff addressed a note to Dr. Wilks, containing the following interesting observations: He pointed out that the furrow was at first, when near the lunula, shallow and difficult to identify, but that when it reached the middle of the nail it was distinct, and often, especially in nails with longitudinal ridges, dotted. The furrow reached the middle of the nail about three months after an illness, but moved onwards towards the free end at different rates

in various cases, the rate increasing as the free edge was approached. As a rule, all the finger-nails were affected, but in some only the right hand showed the mark, and in others only special fingers, the ring-finger most often escaping entirely. Mr. Wagstaff also stated that the furrows could be produced by a local cause, and mentioned a case in which the left hand was injured by a rocket stick, which fractured the metacarpal bone of the index finger, and the arm and hand remained in splints for a month; the left hand only showed the transverse furrows, but on all the fingers.

—The Paris correspondent of the *British Medical Journal* gives what purports to be a sober account of a case of hysteria recently under the care of M. Peter at the Hôpital Necker, presenting the phenomena of sensibility of the integuments to gold, and susceptibility to the influence of medicinal substances at a distance. The patient was a man, who applied on account of contracture of the entire right side, principally in the leg. He is a well-known hysterical subject, and it was on him that the theory of telepathic medicine, broached not long ago by two surgeons of Rochefort, was chiefly based. It was noticed that his skin was extremely sensitive to the contact of certain metals; but Dr. Peter, who is very cautious in accepting such facts, seeing that the patient was an inveterate liar, took every precaution to ensure absolute accuracy in the experiments he undertook. Dr. Peter, as if by accident, touched the back of the man's hand with a gold ring he was wearing. The patient complained of a sensation of pain, and the next morning there was a small blister, as of a burn of the second degree, on the spot touched by the ring. The same day the head nurse, while helping the patient, accidentally touched one of his fingers with her gold chain, and the same result was produced. To prove that there was no trickery, and that the man had not purposely burnt himself with a match, Dr. Peter's assistant, Dr. Caron, percussed the man's back, particularly where his hand could not reach, even with a lighted match, and wherever Dr. Caron's gold ring had touched the skin there was a blister, as in the first case. Other metals similarly applied did not give the same result. Following up these experiments with regard to the influence of medicaments at a distance, the following curious effect was observed: Without the patient being aware of it, a small tube wrapped up in paper, the contents of which were unknown to Dr. Peter himself and to his assistants, was held within about four inches of the back of the patient's neck. In less than ten minutes his face became covered with profuse perspiration, he was seized with nausea, and soon vomited some liquid. On tearing off the paper cover from the tube, it was seen to contain ipæcauanha. Similar experiments with alcohol and opium gave no results whatever.

NEW ENGLAND.

—A sad case is reported in the daily press as having occurred at Medford, Mass., last week. A woman

was confined under the care of her mother, a Mrs. Conner, a practitioner of Christian science, and the patient died of hæmorrhage, while the child perished simply from neglect. The physician called, refused to sign the certificate, and the case came before the medical examiner, who found the facts as stated. The Christian scientist has been arrested for manslaughter.

Miscellany.

PERSISTENT OEDEMA.

Dr. JAMIESON in the *Edinburgh Medical Journal*, March, 1888, refers to two cases simulating myxœdema, reported by Dr. Lassar, at the session of the *Berliner medicinische Gesellschaft*, March 16, 1887. The swollen face, the thickened eyelids and lips, and the puffy enlargement extending from the throat to the ears, are at the first glance the most striking of the features of myxœdema, yet all these were simulated in these two cases. One of these was a young tailor, aged seventeen. Her face was pasty, much swollen, glossy, the opening of the eyelids narrowed, the skin hard. Traced back, there was a history of frequent epistaxis, with nasal polypi, and chronic rhinitis. The latter had recurred frequently, and still persisted. For four years she had suffered from repeated attacks of swelling and redness of the face. At first the swelling entirely subsided, but of late the œdematous condition remained constant, and notwithstanding regular treatment with the constant current, in no degree improved. The spurious erysipelas in this instance was distinguished from the true by the absence of pyrexia; while the rapidity with which the attacks succeeded one another interfered with the activity of the absorptive apparatus, and led to a persistent œdema. The second case was that of a man who suffered from an itchy eruption starting from the angle of the mouth on the right side, attended with acute inflammation and severe swelling, and lasting from eight to ten days. The eruptions recurred in about four or six weeks. These left always behind a degree of thickening of tissue, which gradually became augmented, and in the end produced a very grotesque disfigurement. The countenance became deformed, round like a cannon ball, and occasioned, apart from disfigurement, unendurable annoyance. Under fine scarifications, repeated during more than thirty sittings, and dressing with Lassar's 2 per cent. salicylic vaseline paste, the swelling was materially lessened, as well as the frequency and severity of the attacks.

THE COMBINATION OF SYPHILIS WITH CARCINOMA.

At a last meeting of the Vienna "Medizinisches Doctoren Collegium" according to a Vienna correspondent of the *Medical Press and Circular*, Prof. Lang showed a case in which syphilis was combined with carcinoma. The first respective cases had been communicated by Hutchinson and Langenbeck. Prof. Lang had hitherto had the opportunity of observing four such cases. The carcinoma which developed later on, on the syphilitic soil was each time proved

by histological examination. In the first case which he had observed in 1883, there were besides relapses of iritis and other symptoms characteristic of syphilis; also gummatous ulcerations of the face. Under anti-syphilitic treatment all the ulcerations disappeared, except one which became transformed into a caneroid of the skin. The second case was that of a man, aged forty-six, who had suffered from various syphilitic ulcerations on different parts of the face and body. After anti-syphilitic treatment one ulcer, viz., that under the tongue, remained behind, and became also transformed into carcinoma. In the third case a syphilitic infiltration of the lower lip relapsed at the end of a year, and assumed a carcinomatous character. The fourth case was now brought forward before the Society. The patient presents several scars on the trunk and the face, as well as perforation of the palate and loss of substance of the upper lip. She had been admitted into the hospital during the month of January. Most of the ulcerations were at that time covered with a white scab, but the histological examination of this substance did not reveal any sign of importance for diagnosis. Since the 19th of February current, a small ulceration, which was very indolent, became visible over the hard palate. The part which was excised from it for histological examination was found by Prof. Weichselbaum, of Vienna to be epithelioma. Prof. Lang remarked that these developments of carcinoma on a syphilitic base had not hitherto attracted sufficient attention.

PSYCHIC DISTURBANCES IN RUSSIA.

IGNORANCE, superstition and oppression are soils in which hysterical epidemics are liable to flourish with frightful vigor. A native writer, in an article upon "Mystical Pessimism in Russia," in the *Contemporary Review*, says that "Pessimism is a characteristic feature of all those epochs of history in which the mass of human suffering is at a maximum, and moral aspirations are entirely out of harmony with social conditions. Involved in an unequal conflict with their surroundings, men come to regard life as a terrible burden, and seek refuge in suicide, or in strange, mystical and extravagant theories of society." We find in *Science*, April 13, an extended notice of this paper, which contains much of interest to the student of mental science.

About twenty years ago a peasant in the province of Perm, after spending much time in the reading of religious books, concluded that the end of the world was at hand, and converted his neighbors to his belief. Voluntary suicide was the only release from the misery that surrounded them. A number of men, women and children, including the members of his own family, retired to a forest, where the men dug catacombs, while the women made shrouds. This lasted three days. Then all the disciples, dressed in the garments of death, three times renounced Satan. The leader gave the command, "Take no food and no drink for twelve days, and you shall enter the kingdom of heaven." Then the days of suffering began. A few, more human than the rest, appealed in behalf of the children, whom they saw writhing in agony, and sucking blades of grass or eating sand; but the leader was immovable. At length two of the fanatics could endure it no longer, and fled. This frightened

the band, and the leader announced that the hour of death had come. They massacred the children, and decided to continue the fast. At this stage the police had sought them out, but their frenzy was kindled to the highest pitch. With the prospect of capture before them, a horrible carnage ensued. They killed the women with hatchets, and the efforts of the police only succeeded in saving the leader and three of his associates.

Another instance is that of the monk Falaré, who, not many years ago, went along the banks of the Volga preaching suicide with great success. One night eighty-four persons met in a cavern that had been filled with straw. They began to fast and pray; but one woman fled and informed the police. As their pursuers appeared, they set fire to the straw and threw themselves upon it, killing themselves with hatchets. Many were saved, however, and one of the condemned escaped from prison and continued to propagate the doctrine. More than sixty persons, including whole families, became his disciples. A day was fixed upon which one peasant went to the houses of the others killing men, women and children, all calmly submitting to their fate. The leader then had himself killed. Thirty-five persons, in all, thus perished. These *en masse* massacres are becoming more rare, but all kinds of crimes are still perpetrated as the result of a religious fanaticism. In 1870 a woman threw her child into the fire in obedience to a divine command, and showed no signs of remorse when called to trial. A dozen years ago a man crucified himself, actually nailing his feet and one hand to a cross, and then impaling the other on a nail.

OBITUARY — CORNELIUS REA AGNEW, M.D.

DR. C. R. AGNEW, the subject of this sketch died in New York April 14th, from general peritonitis, the result of peri-typhilitic inflammation, after an illness of but little more than a week's duration. The disease pursued its course to a fatal termination notwithstanding early diagnosis and early operative interference on the part of Drs. Delafield and Sands, who were in attendance.

Dr. Agnew was born in New York on Aug. 8, 1830, and was of Huguenot extraction. His parental ancestors took refuge in North Ireland after the edict of Nantes, and joined the Scotch Presbyterian Church. John Agnew, his grandfather, came to this country in 1786 and first settled in Philadelphia, but soon moved to New York.

At the age of fifteen Dr. Agnew entered Columbia College, from which he was graduated in 1849. In 1852 he received his diploma from the College of Physicians and Surgeons, and soon after was appointed House Surgeon to the New York Hospital, and then its Curator. Then he accepted the position of Surgeon to the Eye and Ear Infirmary, but made it a condition that he should first go to Europe to complete his studies. He accordingly went to Dublin, where he became a resident pupil of the Lying-in Asylum, and attended the clinics given by William Wilde at St. Mark's Eye and Ear Hospital. Then he went to London, following the clinical lectures of William Fergusson. From London Dr. Agnew went to Paris, where he studied under Velpeau, Ricord, Sichel and Desmarres, and Hardy.

He returned to New York in 1855, and began practice. The next year he married Mary, daughter of Lora Nash, a merchant of New York. In 1858, Gov. E. D. Morgan appointed him Surgeon-General of the State of New York, and at the outbreak of the war the Governor appointed him Director of the State Volunteer Hospital, New York. When the United States Sanitary Commission was organized Dr. Agnew and Dr. Elisha

Harris were unanimously elected to the Commission. He was regarded as an authority in the United States Sanitary Commission, and although he had a large private practice he devoted all the rest of his time, at great personal sacrifice, to this service. The life-saving work of the Commission at Antietam, the battles of the Wilderness, and the relief to the wounded and sick soldiers who returned from Southern prisons was made so successful principally by the carefully arranged plans of Dr. Agnew executed under his own superintendence.

Dr. Agnew was one of four gentlemen who founded the New York League Club, which gave such material assistance to the government during the war, and he became one of its vice-presidents.

In 1866, at the request of the Faculty of the College of Physicians and Surgeons, he established an ophthalmic clinic there, and in 1869 he was elected Clinical Professor of Diseases of the Eye and Ear. The following year he organized the Brooklyn Eye and Ear Hospital, and also the Manhattan Eye and Ear Hospital, the latter in New York. He had been appointed in 1865 one of the managers of the New York State Hospital for the Insane at Poughkeepsie, and was twice reappointed to that office.

As early as 1859 Dr. Agnew was elected a trustee of the New York public Schools, and was made president of the board. Several years later he was selected a trustee to organize a School of Mines in Columbia College, and in 1874 he became a trustee of that college. In 1872 he was chosen President of the Medical Society of the State of New York. He was Secretary of the first New York Sanitary Reform Association, and one of the committee which made the first draft of the health laws of the city. He belonged to a large number of medical and scientific societies at home and abroad. He was a fluent lecturer, and was widely known as an authority on ophthalmology. He made valuable contributions to medical literature, among which were "A Contribution to the Surgery of Divergent Squint," "Trephining the Cornea to Remove a Foreign Body," and "Cathoplasty as a Remedy in Certain Diseases of the Eye."

Dr. Agnew's death causes a loss to the medical profession and to society which will not easily be made good. His interests covered a variety of subjects, in which his labors were always well-directed and almost always fruitful. His life was terminated prematurely at the early age of fifty-eight years, but his activity had been such as to lead many to suppose that he must have been much older. He leaves a widow, one son and seven daughters.

Correspondence.

FIVE LIVING GENERATIONS.

BROOKLINE, April 23, 1888.

MR. EDITOR,—Dr. Root, of Georgetown, in the last number of the JOURNAL mentions a family in which there are, or were (for some may have died since the date of his letter) six living generations. After landing his name down to posterity by recording this extraordinary case he challenges your readers to produce even *five* generations.

I am happy to say that I, as one of that large and interesting class known as "constant readers" can produce an instance of five living generations, the fourth and fifth living in this town within a short distance of my house, and the three other generations all living in Natick. Their ages are as follows:

Great-great-grandmother	81 years.
Great-grandmother	63 "
Grandmother	42 "
Mother	29 "
Child	5 months.

The great-great-grandmother was married at 17; the great-grandmother at 19; the grandmother at 17, and the mother at 19. Yours truly,

WALTER CHANNING, M.D.

OPERATING FOR ADENOID GROWTHS.

CLARKSVILLE, TENN., 18th April, 1888.

MR. EDITOR,—Having read with great interest the articles of Drs. Hooper and Blake, on "Adenoid Growths, Their Diagnosis and Treatment"; also Dr. Farlow's letter announcing the fact of the "impossibility of blowing the nose" when this condition exists, I desire to call their attention, as well as that of others interested in the subject, to Dr. J. C. Warren's method of operating for Cleft Palate, published in the JOURNAL several years since. The patient, after being anaesthetized is moved upwards on table until the head hangs. The surgeon on a stool drawn close operates, allowing all hæmorrhage to escape through nostrils.

It occurs to me this would entirely obviate the "danger of blood being sucked into the larynx," and also of "clot becoming wedged in the glottis," unless the growths so fill the nasal cavity as to prevent its escape.

Respectfully yours,

T. D. JOHNSON, M.D.

DIABETIC FOODS CONTAINING STARCH.

BOSTON, April 24, 1888.

MR. EDITOR,—Mr. W. L. Johnson's letter in the JOURNAL of April 19th, commenting on my article on Diabetic Foods misquotes and misleads. Section 7 is quoted: "Dr. Johnson's Educators. These biscuits are recommended very strongly by the seller who assured me that they were absolutely free from starch," and then Mr. Johnson adds "For light on this point let your readers consult my Educator and other circulars." I have consulted all of the latter including even those setting forth the preposterous claims of the "Olive Branch Radical Cure for all Female Diseases" and of "Garfield Tea, or Liver and Kidney Cure," but find no further light. Perhaps I can myself furnish some. When I made my purchase of diabetic biscuits Mr. Johnson was present, and himself informed me that the biscuits were absolutely free from even traces of starch, that the process owned by his company was the only one for the proper elimination of the starch, and that he guaranteed them in every way. I found that they contained 71.43 per cent. of starch. I made a second visit to ask if these biscuits had any particular trade name, and was told they, like all the other biscuit of this make, might be called for as "Educators," or "Diabetic Educators." I made to-day another call and incidentally bought another pound of these same biscuits, which were again guaranteed as *free* from starch. It is perhaps unnecessary to add that I was not known as the writer of the article. The gluten flour and special diabetic food from the same establishment yielded respectively 62.91 per cent. and 54.88 per cent. of starch (warranted absolutely free), and not 30 per cent. and 23 per cent. as Mr. Johnson has misquoted. The latter figures are for the bread made from these flours. The figures for the gluten (Educator) biscuits are carefully left unquoted.

Notwithstanding this I am accused with dishonesty and fraud, and he commends a Graham wafer of another's make with its 15.15 per cent. of starch as a superior food to mine. Mr. Johnson knows that the latter part of this is untrue. To quote my own words, "Compared with the diabetic biscuits above mentioned, the Graham wafer may be almost regarded as a superior form of diabetic food. It contains a smaller percentage of starch than the Educator with its 71.43 per cent.," etc., etc. Mr. Johnson continues, "The fact that absolute gluten has never been produced except in the laboratory, is quite significant in this connection," and I will add that his guarantee that his biscuit are made of absolute gluten and water only, is quite significant in another. I did not, in my article, accuse Mr. Johnson personally "with dishonesty and fraud," and at the present time such an accusation would be quite superfluous, since he stands self-accused. Yours truly,

CHARLES HARRINGTON, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 14, 1888.

Deaths reported 1,967: under five years of age 695; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 257, acute lung diseases 243, consumption 300, diphtheria and croup 89, scarlet fever 48, diarrhoeal diseases 29, typhoid fever 22, measles 17, whooping-cough 15, cerebro-spinal meningitis 12, erysipelas nine, puerperal fever eight, malarial fever seven, small-pox five, remittent fever one. From diarrhoeal diseases New York 16, Philadelphia six, Boston three, Washington, Pittsburgh, Worcester and Fall River one each. From measles, Baltimore nine, New York five, Boston, Washington and Gloucester one each. From whooping-cough New York and Boston four each, Philadelphia three, Washington two, Fitchburg and Baltimore one each. From cerebro-spinal meningitis, New York six, Philadelphia two, Boston, Washington, Fall River and Newton one each. From puerperal fever, Washington four, Pittsburgh three, Boston one. Malarial fever New York seven. Remittent fever, Baltimore one. From small-pox New York four, Philadelphia one.

In the 28 greater towns of England and Wales with an estimated population of 9,398,274, for the week ending March 31st, the death-rate was 21.5. Deaths reported 3,881: infants under one year of age 913; acute diseases of the respiratory organs (London) 460, whooping-cough 156, scarlet fever 65, measles 12, fevers 35, diarrhoea 31, diphtheria 24, small-pox (Sheffield) 19, Blackburn three, Nottingham two, Bristol, Manchester and Hull one each) 27.

The death-rates ranged from 15.1 in Birkenhead to 33.3 in Blackburn; Birmingham 19.5; Bolton 31.3; Bradford 21.3; Leeds 22.3; Leicester 21.3; Liverpool 22.4; London 20.3; Manchester 26.4; Newcastle-on-Tyne 25.6; Norwich 22.3; Nottingham 21.7; Portsmouth 22.1; Sheffield 21.2.

In Edinburgh 22.8; Glasgow 27.5; Dublin 31.2.

RESIGNATION AND APPOINTMENT.

Dr. William A. Gorton, superintendent of the State Lunatic Asylum, Danvers, Mass., has resigned his position, having been appointed superintendent of the Butler Josiah Hospital, of Providence, R. I., where he succeeds the late Dr. William B. Goldsmith, who was himself called thither from Danvers.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 14, 1888, TO APRIL 20, 1888.

STERNEBERG, GEO. M., major and surgeon. Having been instructed by the President to proceed to the Island of Cuba, for the purpose of continuing his investigations of the methods of preventing the spread of epidemic diseases, will in connection with his present duties, report to the Secretary of the Treasury for further instructions. S. O. 89, A. G. O., April 18, 1888.

EWEN, CLARENCE, captain and assistant surgeon. Granted leave of absence for six months, with permission to go beyond sea. S. O. 85, A. G. O., April 13, 1888.

ARTHUR, WM. H., captain and assistant surgeon. Ordered from Fort Niagara, N. Y., to Fort Bowie, Ariz., to take effect on the expiration of his present leave of absence.

BLACK, CHAS. S., first lieutenant and assistant surgeon. Ordered from Fort Davis, Tex., to Fort Sidney, Neb. S. O. 86, A. G. O., April 14, 1888.

CROSBY, WM. D., first lieutenant and assistant surgeon. Ordered for duty at Jefferson Barracks, Mo., after being relieved by Assistant Surgeon Wm. H. Arthur, and upon the expiration of the leave of absence granted him in S. O. 60, A. G. O., March 14, 1888. S. O. 86, A. G. O., April 14, 1888.

APPOINTMENT.

RAFFERTY, OGDEN, to be assistant surgeon with rank of first lieutenant, March 26, 1888.

PROMOTION.

GIRARD, JOSEPH B., captain and assistant surgeon. To be surgeon with the rank of major, March 22, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 21, 1888.

ROADS, A. C., medical inspector. Detached from special duty, New York, and waiting orders.

HENNEBERGER, L. G., passed assistant surgeon. Detached from Naval Hospital, New York, and to special duty attending officers and families, New York.

The meteorological record for the week ending April 14, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.	
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Daily Mean.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	Duration, Hrs. & Min.	Amount in Inches.

OFFICIAL LIST OF CHANGES OF POSITIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDED APRIL 21, 1888.

HUTTON, W. H. H., surgeon. To proceed to Biloxi, Miss., on special duty. April 21, 1888.

LONG, W. H., surgeon. Granted leave of absence for fourteen days. April 21, 1888.

SAWTELLE, H. W., surgeon. Granted leave of absence for seven days. April 21, 1888.

URQUHART, F. M., passed assistant surgeon. Granted leave of absence for seven days. April 10, 1888. To assume temporary charge of Cape Charles Quarantine Station. April 17, 1888.

WHITE, J. A., passed assistant surgeon. Relieved from quarantine duties at Supleto Station. April 21, 1888.

WILLIAMS, L. L., passed assistant surgeon. Relieved from duty at Marine Hospital, Boston, Mass. To assume charge of Cape Charles Quarantine Station. April 17, 1888.

BRATTON, W. D., passed assistant surgeon. Relieved from duty at Marine Hospital, San Francisco, Cal.; detailed as medical officer, Revenue Steamer "Bear," during summer cruise. April 19, 1888.

SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.—There will be a meeting of this Section at 19 Boylston Place, on Wednesday evening, May 24, at eight o'clock. Communications: Dr. E. H. Bradford, "Two Cases of Direct Incision into the Hip Joint in Early Hip Disease." Dr. C. E. Porter, "Five Cases of Perineal Section," (reported by Dr. A. K. Stone). Dr. M. H. Richardson, "A Case of Supra-Pubic Cystostomy for Tumor of the Bladder." G. H. MONKS, M.D., Secretary.

SUFFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at 19 Boylston Place, on Saturday, April 28, 1888, at 8 P.M. Paper by Dr. J. J. Putnam, "Paralyses Caused by Medicinal Doses of Arsenic; with Remarks on the Diagnosis of Multiple Neuritis." Reports of the Treasurer, Librarian, and Committee on Social Meetings. Election of officers. Supper after the meeting. Members desirous of being appointed delegates to the American Medical Association will please make known their wishes to the Secretary.

HERBERT L. BURRELL, M.D., Secretary.

PLYMOUTH DISTRICT MEDICAL SOCIETY.—At the annual meeting of the Plymouth District Medical Society, held at Brockton, April 18th, the following officers were elected: President, Dr. J. B. Brewster; Vice-President, Dr. A. E. Paine; Secretary and Treasurer, Dr. A. V. Lynn; Librarian, Dr. A. A. MacKenzie; Committee on Trials, Dr. H. N. Jones; Reporter, Dr. A. V. Lynn; Censors, Drs. E. A. Chase, W. P. Chisholm, W. C. Keith, F. J. Ripley, F. G. Wheatley; Councilors, Drs. J. H. Averill, H. F. Burden, J. C. Gleason, B. F. Hastings, A. Millitt, A. E. Paine; Committee on Nominations, Dr. J. C. Gleason; Orator, Dr. R. Hammond; Delegates to American Medical Association, Drs. J. B. Brewster and H. W. Dudley.

A. V. LYNN, Secretary.

AMERICAN MEDICAL ASSOCIATION.—The Thirty-Ninth Annual meeting is to be held in Cincinnati, May 8th, 9th, 10th and 11th. The General Meeting will be held in the Cincinnati Music Hall and the Sectional Meetings in adjoining rooms in the same building. Among the addresses in general session are, on

the first day the Annual Address, by President A. Y. P. Garrett, of Washington; on the second day, Address on General Medicine, by Prof. Roberts Bartholow, of Philadelphia; on the third day, Address on General Surgery, by E. M. Moore, M.D., of Rochester; on the fourth day, Address on State Medicine, by H. P. Walcott, M.D., of Boston.

In the Section of General Medicine the mechanism and treatment of pneumonia receives special discussion, together with diseases of the stomach. In the Section of Surgery, the appendix vermiformis, and its affections. In the Section of Diseases of children, infant feeding, and treatment of pseudo-membranous laryngitis by tracheotomy and intubation. The names of gentlemen announced to discuss these and other interesting subjects are well known, and a large number of papers are announced in all the sections.

The Committee on Railroads have secured a reduction on the certificate plan from all railroads entering the city of Cincinnati. The rate will be full fare going to the meeting of the American Medical Association, and one-third fare returning. Physicians will please ask for a blank certificate at the railroad office at the time they purchase their tickets, which certificate will entitle the holder thereof to a one-third rate returning. Drs. George Purviance and William Judkins are the local subcommittee in charge of railroad and hotel accommodations.

DEATH.

Died in New York, suddenly of heart disease, April 22d, Edward Greely Loring, M.D., aged forty-eight years.

ENTRANCE EXAMINATIONS, MASSACHUSETTS INSTITUTE OF TECHNOLOGY, 1888.

Entrance examinations will be held at the Rogers Building, 187 Boylston Street, Boston, Mass., on Thursday and Friday, May 31st and June 1st. A second series, for those unable to be present then will be held on September 18th and 19th. The examinations will begin at 9 A.M., and attendance on both days of one month or the other will be required.

For the convenience of applicants outside New England, entrance examinations will be held on May 31st and June 1st, in the following cities: New York, Philadelphia, Montreal, Chicago, St. Louis, Cincinnati, San Francisco, Washington, Nashville, Tenn., St. Paul, Minn., Pittsburgh, Santa Fe.

A STUDY OF ARTERIAL TENSION IN NEURASTHENIA.¹

BY S. G. WEBBER, M.D.

It is scarcely necessary to say that variation in the amount of blood contained in the brain, and especially irregularity in its distribution, may give rise to abnormal phenomena. This has been known for many years. Mosso was among the first to give a practical demonstration of the ease and rapidity with which the amount of blood in the brain may vary. He was fortunate in having patients who had lost portions of their skull, the brain being thus covered only by soft tissue. He fitted instruments to register the variations of circulation under different conditions.

He learned, by comparing the cerebral circulation with that of the arm that when there was a marked increase in the amount of blood flowing to the brain, the vessels of the arm were less full, and the reverse. Any intellectual operation, as multiplying two numbers, or any emotional excitement, or a sudden surprise, were sufficient to send more blood to the brain. Under certain conditions, the form of the tracing changed both for the brain and for the arm pulse.

These investigations have only an indirect bearing upon the subject which I now wish to bring to your attention; they are chiefly of value as showing that there is a marked relation between the circulation of the brain and that of the arm.

Dr. Anjel² has studied the circulation in the arm in neurasthenia, using the plethysmograph. It will be sufficient to mention that he found, when the brain is active, the amount of blood in the arm is diminished. In health, after the mental effort has ceased, the return of the normal circulation is rapid, and soon the previous equilibrium is re-established. In cases of neurasthenia the contraction of the vessels in the arm is of only short duration; they soon dilate. This change in the size of the arm is repeated at irregular intervals so long as the mind continues in action, and for a time afterwards, so that the normal equilibrium is only slowly re-established. Also, the circulatory disturbance is excited by very slight mental impressions, which have no influence upon healthy persons.

The prominent fact in Anjel's experiments is the instability of the vaso-motor innervation. There is a lack of healthy tone in the vessels.

This is the opinion generally held in regard to neurasthenia. I do not know that any special effort has been made to study the condition of the bloodvessels in neurasthenia with the aid of the sphygmograph. I have taken a large number of tracings in such patients at the Adams Nervine Asylum, and propose to study them with the purpose of learning, if possible, whether by this means the above opinion can be proved to be well founded, and also whether the sphygmograph can be depended upon as a guide in diagnosis, prognosis, or treatment.

Neurasthenic patients may be divided into several classes: First, those in which the vascular tension is nearly or quite normal. There are a few such, who seemingly have been only temporarily run down, and quickly recover.

Another class may be formed of those who, at first,

show a decided loss of vascular tone, who, after a course of treatment, regain a normal tension. These usually recover in a longer or shorter time. Those whom I have had under my care have not always regained health while under observation, but I have had subsequent information from many who have continued to steadily gain, and have recovered a fair amount of health.

A third class are those whose vascular tone is very much below normal, who show a variable condition of the vaso-motor system, sometimes apparently gaining a little, then losing ground, but on the whole making no substantial progress. Many of these have a hereditary tendency to an unstable nervous equilibrium, or there is some condition of the system that reacts unfavorably upon the circulation. These cases do not improve much, and whatever is gained is of very doubtful permanency; there is a lack of vascular stability which is unfavorable to recovery.

I have had a few cases where the earlier tracings showed a nearly normal condition of the bloodvessels, but later tracings were less favorable. In such cases there has usually been some cause to which such unfavorable change could be ascribed. One patient was doing well, gaining, with a good pulse; her son-in-law, upon whom she was partially dependent, met with an accident which was nearly fatal. This shock completely upset her, and the vessels afterwards showed a very great lack of tension.

Some of the worst cases show a great variation within a few minutes, one tracing being only slightly variant from the normal, the next, taken within five minutes, showing a great loss of tension.

Tracing No. 1 is quite normal, and may represent that obtained from the most favorable cases.

No. 1.

CASE I. Miss A., aged twenty-five, had taught school until entirely used up. She was a pale, weak, nervous-looking woman. She had several hysterical attacks, with loss of consciousness and delirium, at the catamenial period. These began with severe headache. There was no special uterine lesion, simply tenderness of all the pelvic organs. There was a murmur with the second sound over the aorta when she entered, which was supposed to be due to the anemia.

Several tracings of the pulse were taken at different times during her stay. They were all very similar, and nearly normal.

She gained much, continued to improve after leaving, and after a year's rest was able to teach again. She has taught nearly two years, and when last seen was in good health; walked about three miles nearly every day. She took a small school, so as not to overtax her lately regained strength.

The second group consists of tracings from those patients who showed loss of vascular tone, but recovered a nearly normal tension and had a corresponding gain in symptoms.

CASE II. Miss D., aged thirty-one, was an interesting patient. She had never been strong. She was run down by care of mother who was paralysed. She had a distinct hysterical propensity to exaggerate

¹ Read before the Boston Society of Medical Sciences.² Archiv. f. Psychiatrie, etc., xv, 1884, p. 618.

and dwell upon her symptoms. When talking she winked her eyes rapidly, spoke in a complaining, whining tone. The real symptoms were those of nervous depression, headache, dizziness, insomnia, dyspepsia, *et omne id genus*. There was no ovarian tenderness; the lower parts of uterus and cervix were tender, there was extreme anteversion with slight flexion at junction of neck and body, a probe entered with difficulty, there was an ulceration with granulation about three-fourths of an inch in diameter around the os. A very faint murmur was heard with the first sound, and there was a slight increase of area of cardiac dulness.

The tracings showed a variation from time to time, irrespective of the medicine taken. The first tracing (No. 2) was not taken until the patient had been at the asylum three months. This shows a marked loss of tension. The next (No. 3) six weeks later is quite

No. 2.

No. 3.

normal, but two days after the tension was again diminished. A month later there was less energetic action of the heart and a nearly normal tracing, with very slow descent. On the whole the vascular tone improved, the symptoms improved, the uterine ulceration was nearly or quite cured. She was examined some time after leaving and found to have recovered, and later gained in health and nervous vigor.

CASE III. Mrs. L., aged thirty-three, had had various local treatment for uterine disease. There was an enlarged uterus, probe passed in more than three inches, the cervix was enlarged, almost purple in color, bled easily, and presented many small spots of erosion. The symptoms were those of nervous prostration with headache, backache, irritability of temper, hysterical condition. She said any attempt to do for the uterus had only upset her, so she was simply given hot douches when it seemed necessary.

At entrance the tracing (No. 4) is seen to be characteristic of loss of tension, there is a slight tendency to dicrotism, the pulse is rapid.

After six months (No. 5) the pulse is much more

No. 4.

No. 5.

nearly normal, but of irregular strength. The tension is improved, not any tendency to dicrotism, in one or

two spots the needle seemed to catch in the paper and make a slightly toothed summit.

This patient was very much benefited by treatment and continued to improve after leaving.

CASE IV. Miss F., aged thirty-seven, was a patient who had suffered long from nervous prostration, of a very decidedly hysterical tendency, without any convulsive or other attacks; who, when fairly strong, had pretty good self-control. There was no complication. The patient was very fleshy and her nutrition was not in a good condition.

The tracing (No. 6) taken about two weeks after she came shows a great lack of vascular tension. She gained slowly, lost some of her superfluous flesh, and five months after gives a tracing (No. 7) much more

No. 6.

No. 7.

nearly approaching health. There seems to be even a slight excess of tension. She was at this time taking no medicine to increase the tension. She continued to gain after leaving here, though probably she will never be very strong. Urine 1040 acid on entering.

CASE V. Miss M., aged thirty-two, had quite marked hysterical attacks before coming to the asylum. She was underfed and a simple case of nervous exhaustion without any complication. A tracing (No. 8) taken a few days after her admission, shows a cer-

No. 8.

tain amount of loss of tone in the bloodvessels, not excessive; the first descent is too sudden. There is also an irregularity in the tension, the first part of the tracing the descent being more gradual at the beginning than near the centre of the tracing. After three months there was a decided improvement, the tracing (No. 9) became quite natural and healthy.

No. 9.

This patient was very much relieved; but her subsequent history is not known.

The next case is one in which there was an irregular gain and loss. The patient gained much while in the asylum, but not so much as those whose cases have been just recorded. This may be considered as intermediate between those first given and the next class.

CASE VI. Miss J., aged thirty-three, had suffered for a long time with weakness and pain of back, headache, a confused feeling in head, inability to read long, and a sense of general exhaustion and tiredness. She was able to take only a small amount of nourishment at first, but later could eat well, though occasionally she had attacks of nausea and was obliged to live lightly. She had extreme anteversion of uterus, and after exertion or walking complained of distress. The displacement was rectified as much as possible, though owing to tenderness very little could be done. She probably exaggerated her discomforts to gain more attention. The heart sounds were normal.

The tracing (No. 10) taken soon after her admission, shows a strong impulse unresisted by the arteries, and after exertion or walking complained of distress nearly to the original level, then a slight dicrotic rise.

The next tracing (No. 11) taken three months

No. 10.

No. 11.

later, after a long rest in bed, good feeding and a general gain shows a less sudden descent, an absence of dicrotism, and a near approach to the normal, but much loss of tension. Five months later there is again a tracing very similar to the first; less dicrotic. Some months later (No. 12) the tracing is approach-

No. 12.

ing more closely the normal, but the tension is still rather defective.

This patient gained after leaving the asylum; several months after was strong but still had an appearance as if lacking in nervous force. She called herself well. It is not likely that she can withstand much of a strain.

The following are cases in which there was little or no gain, the condition of the vessels remained unfavorable. These belonged to the third group of cases.

CASE VII. Miss G., aged thirty-nine, had a fall from a horse and hit the end of her spine; she suffered from backache and headache, was tired and looked worn.

There was very little difference between the tracings taken when she entered (No. 13), and when she

No. 13.

left (No. 14). She gained from her rest and quiet in

No. 14.

that she had less pain and was able to be about with much less discomfort. Nothing has been heard from her since a few months after she left; it is doubtful if the gain proves permanent.

CASE VIII. Miss H., aged thirty-one, fell down stairs when twenty-one years old, hurting her back; she was in bed four years or more; she suffered much from pain in abdomen. Afterwards she had attacks during which she was dizzy and then unconscious, with weakness and trembling afterwards. She was obliged to catheterize herself; she had aphonia which came on suddenly at the time of her father's death. Soon after she entered, her mother died suddenly, which was a shock to her, after which she was less well and more hysterical. There was partial hemianesthesia, which after a convulsive attack became more marked. There was a neurotic history on the father's side; he, his three brothers and nine sisters had sick headache, and the patient has three brothers, out of six, and two sisters who have sick headaches. The father suffered from some wasting disease for thirty years, perhaps progressive muscular atrophy.

The first tracing (No. 15) was taken soon after entrance and shows excessive loss of tension and hyperdicrotism. A peculiar pulse which is seen occasionally in very excitable patients. The second tracing (No. 16) presents a loss of tension, the dicrotism is well-marked. The third tracing (No. 17) is much more

No. 15.

No. 16.

No. 17.

nearly normal, but there is still loss of tension. At the time when the last tracing was taken she had improved very much and had been able to speak aloud for a few days. She subsequently became worse and had a very greatly modified or aborted hysterio-epileptic attack.

She subsequently improved again, but a year after leaving was still far from well.

CASE IX. Mrs. G., aged forty-five years, had passed the menopause. She had from girlhood had sick headaches, which were probably hereditary. Her mother had these, and was very nervous; her maternal grandparents died of phthisis; she has five broth-

ers and one sister, all nervous; her daughter is hysterical. The patient was full of all sorts of notions, was a firm believer in "mind cure," but had only been slightly benefited by it; she shed tears frequently every day for every and no cause. She was thin, emaciated, evidently half-starved. She had spells of low spirits. She gained in flesh and spirits, and after five months said she had never felt so well.

The tracings show a variation which is interesting. The earliest (No. 18),* taken about a month after entrance, shows an increase of tension; the impulse of the heart did not drive the needle very far; the descent is gradual, commencing only after a brief interval. Two weeks later a tracing showed a decided loss of tension; about three weeks later (No. 19), the same loss of tension, but a little more tendency to dicrotism; yet a second tracing taken on the same occasion gives a rather better showing. A tracing (No. 20) taken after she had been four months under treat-

No. 19.

No. 20.

ment shows stronger impulse, but there is not a return to the normal tonicity of the arteries.

Although this patient felt so well and was so very much benefited, I think it is very doubtful if the improvement will be permanent. There is probably a too radical defect in the condition of the vessels, or rather of the vaso-motor nerves, and I doubt whether at her age permanent recovery of tone can be expected in one with such a hereditary tendency.

CASE X. Miss W., aged thirty, was running down during several years. She had backache, headache, tenderness over some of the vertebrae, generally weak, with little endurance, insomnia, anorexia, and other symptoms of general nervous depression. There was retroversion and some excoriation about the os, with much tenderness. She had attacks of palpitation, which at times gave her much discomfort; no abnormal sounds were discovered.

The first tracing (No. 21) was taken soon after she came; the second (No. 22) was taken during an

No. 21.

No. 22.

attack of palpitation; the fourth (No. 23) was after she had gained much, was up much of the time, and

* Omitted by mistake.

going outdoors daily. A later tracing showed, again, loss of tension, and was far from normal.

No. 23.

This patient continued to gain slowly after leaving, but eighteen months afterwards was by no means well.

CASE XI. Miss M., aged twenty-seven, had had sick headaches very much; contracted malarial fever on Staten Island. She had various nervous symptoms, as backache, trembling, staggering, faintness; the headache was continuous with periods of exacerbation. There was special tenderness over the left ovary. There was great tenderness on vaginal examination, a small spot of excoriation about os.

Her father, mother, sisters, and brothers are subject to sick headache; her grandmother had headaches, her grandfather was insane when he died. A female cousin, nineteen years old, and a male cousin, fifteen years old, have sick headaches. Fourteen other cousins are young, one aunt and three uncles have sick headaches; several in paternal grandfather's family are free from trouble.

The first tracing (No. 24) was taken the day after admission; the second (No. 25), hyperdicrotic, was taken after a severe headache and attack of pain in region of left ovary; the third (No. 26) was taken

No. 24.

No. 25.

No. 26.

during an exacerbation of headache, and is the nearest normal of any. A fourth one was taken four months after the first, and showed almost exactly the same characteristics.

The patient's general condition improved, the headaches were less severe, and she had periods of freedom from pain. She did not recover, and there seems very little prospect of recovery.

In view of this and some other cases, the question readily suggests itself whether unstable vaso-motor action and loss of tone may not be hereditary and constitutional, and such persons be unable to endure even moderate strains in life.

CASE XII. Miss W., aged sixteen years, ten months, had hysterical aphonia and ptosis; she had two or three attacks of hysterical spasms.

The tracings show decided loss of tension and ir-

regular innervation of the arteries. The first tracing showed considerable loss of tone in the vessels. The second tracing (No. 27) was taken a few days before she began to talk aloud. The third tracing (No. 28), was taken the day after she stopped talking because some request was refused; she was much agitated at the time. When the fourth tracing (No. 29) was

No. 27.

No. 28.

No. 29.

taken she had been gaining in strength, and was less nervous; she seemed more willing to follow directions, but still could not talk. After leaving she still improved, and I heard that in the afternoon of the day she left she spoke aloud. In the morning she would or could not make a sound. This is a good example of the instability of the arterial innervation in hysteria, the vaso-motor nerves being as irregular in action as other parts of the nervous system.

CASE XIII. Mrs. P., aged thirty-two, had been run down for some time. The chief discomfort was sick headache and pain in back of neck, with neuralgia about the face.

The first tracing (No. 30) was taken soon after entrance, and is quite normal. One (No. 31) taken soon after a headache showed a lack of tension.

No. 30.

No. 31.

She gained decidedly, and after leaving continued to gain in strength, though, if she over-exerted herself, she was liable to have an attack of headache. The other pains disappeared or were very much diminished.

I give two tracings from a patient who had attacks of severe pain. They seemed to arise from the ovaries, or from some of the sympathetic ganglia in the abdomen. The first (No. 32) was taken before the pain; the second (No. 33) when the pain was at its height. The change in the tracing was probably due to the commotion caused by the pain.

In conclusion, then, it may be said that the sphygmo-

No. 32.

No. 33.

graph is an aid in determining the amount of exhaustion; and by comparisons of tracings taken at intervals, the progress of the patient towards recovery can be estimated. A fictitious gain can be recognized, as distinguished from a real gain; no gain being permanent unless the tension of the arteries is permanently restored. A patient's future prospects of health can be calculated with more certainty by an occasional use of the sphygmograph. It is sufficient to take a tracing once in two or four weeks.

THE TREATMENT OF LATERAL CURVATURE.¹

BY E. H. BRADFORD, M.D.

In the whole range of surgical literature, hardly a more uninteresting chapter can be found than that on lateral curvature. Even the pictures are repellant with the endless detail of appliances, from the beaten brass cuirass of Ambrose Paré and the later spinal couches, to the modern plaster-jacket and its variants.

The subject, however, is an important and, in reality, not an uninteresting one, and the treatment, prognosis, and diagnosis of the affection have been by no means put before the profession as clearly as could be desired. As many questions in the matter are still *sub judice*, and there is still a great variety of opinions as to proper treatment, a satisfactory presentation of the subject is still impossible. Some discussion based on experiments and experience with a number of cases will, however, perhaps be permissible.

The methods to be employed in treatment may be grouped as follows: (1) postural; (2) gymnastic; (3) mechanical; (4) rest.

These methods, as will be seen, are especially suitable to particular classes of cases, and they may be severally needed, either alone or in combination.

By the postural method is meant not only the avoidance of all faulty positions and vicious attitudes, but the correction of such vicious habits of attitude. It is practically the medical analogue of the "setting-up drill" of raw recruits in the army. In fact, in some localities, the services of a Prussian drill-sergeant are procured to drill stooping school-girls. The method has been systematized and given a scientific basis by Mr. Bernard Roth, who, with the addition of gymnastic exercises, both active and passive, has developed a most excellent system of treatment. The essential feature of this method is that the peculiarity in attitudes of each patient is carefully noted, and the position most nearly approaching the normal possible to

¹ Read before the Boston Society for Medical Improvement, April 9, 1888.

the patient is found, and that this position is carefully maintained, as far as possible, in the exercises prescribed. The method has been fully described by him, and the details can be found in his writings, and deserves more full description than can be given in the limits of this paper.²

In addition to the gymnastic and postural exercises which are prescribed, and which can occupy only a small portion of the day, care should be taken that the position assumed while sitting, standing, or lying should be as nearly as possible what is desired. The position in sleep is with difficulty controlled without some restraining appliance. The position, in the lighter cases, is not of great importance, as, in a hard bed, without a thick pillow, the chief cause of the development of the deformity, namely, superincumbent weight, is removed. In the usual deformity, that is, right dorsal convexity, the patient should not be allowed to lie upon the right side, with the arm under the pillow, but should lie upon the left side. In curves chiefly of the lumbar region, this is of less importance; the patient should be directed to lie on, or in a position to throw up the retreating hip, possibly with a pillow placed under the hip.

In cases where both curves are equally important, that is, the dorsal and lumbar, the patient should be required to lie upon the back. In severe cases some modification of the spinal couch is necessary, as will be mentioned later. Attitudes in standing should be simply that the patient be required to stand upon both feet equally. Practically, it is advisable that patients of this sort should not be allowed to stand still for any length of time, but that, when erect, they should walk about, or be directed to change their position frequently. The importance of sitting properly is manifest, and is illustrated by the well-known instance of the development of lateral curvature, with curves in opposite directions, in twin sisters who sat next each other upon the same bench at school, and who habitually leaned in opposite directions on the desk in front of them.

The question of school desks and chairs need not be entered upon, as the subject has already been fully discussed. It cannot, however, be too often urged that the school seats, as commonly used, are not properly constructed.³

The question of chairs is as important at home as at school, and it is a matter of surprise how few "easy chairs" are really comfortable to persons with backs with weak muscles. To ordinary individuals with backs of ordinary strength chairs are comfortable, as they relieve the lower part of the body of the weight of the upper, and partly support the back muscles from the strain of steadying the trunk. They rarely, however, are suitable to relieve the back muscles from being placed on the stretch. This will be seen in the following diagram (No. 1):

In fact, to most individuals, most of the easy chairs are practically but a support on which they can lean.

A chair, to be thoroughly a support, should allow the lumbar spine, that is, the hollow of the back, the upper part of the sacrum, to press against the back of the chair. The back should slope backwards slightly, but, if it reaches to the shoulders, it should not push the shoulders and head forward. Such chairs are seen

where the matter of comfort is carefully considered, for example, in some of the parlor cars, in some of the

Diagram 1.

first-class carriages in European countries, in seats for hire on the boulevards in Paris, in the parks in London, and in some of the public squares, such chairs may be found; but they are not, as a rule, seen in our furniture warehouses, where the matter of appearance and fashion is of prime importance. In fact, tradition has dominated the matter; and the chair of the ancients, as seen in the antique statues, is as faulty as our own.

The straight-backed chairs of our ancestors, furnished with a narrow seat, enabled the back to be supported, but is by no means an easy chair. If easy chairs are rarely suitable for adults, they certainly do not fit children; the backs being too high for their shoulders, the seats too deep for their thighs, so that, in the easy chair the child naturally assumes faulty positions, curling themselves up, sitting with their legs twisted under them, to obtain rest. In fact, the habits of the Japanese, who rest by sitting on the heels, is less dangerous to the backs of growing girls than the easy chairs furnished in ordinary households.

In severe cases, with extremely weak backs, it is advisable that the patient have a chair specially constructed to be used if he is to sit for any length of time. Such chairs should be furnished with a book rest.

The gymnastic method consists of gymnastics designed for strengthening such muscles as are needed for holding the trunk in a proper position. It is especially suited for cases of flexible curves, where the muscles are manifestly incapable of holding the trunk in proper position, and where rest is sought in faulty positions. But the gymnastic method should form the foundation of almost all methods of treatment of lateral curvature. Details of special exercises will not be given in this paper, but will be reserved for a subsequent paper.

MECHANICAL METHOD OF TREATMENT.

The mechanical means used are for the purpose of either (a) limiting, checking or preventing faulty attitudes; (b) for exerting direct pressure upon the projecting ribs or hip; or for (c) absolutely untwisting the curves.

To understand the first it is desirable to bear in mind the faulty attitudes most frequently assumed by patients with flexible lateral curves, as follows: (1) the elevation of the shoulder, the dropping of a shoulder; (2) the tilting of the pelvis, raising one hip; (3) leaning the trunk to one side.

The appliances used vary in effectiveness from simple straps or springs to fixed corsets or heavy braces.

(1) For the first purpose, that is, prevention of the elevation of the shoulder, a suitable shoulder-strap will be sufficient. This can be furnished by an ordinary cloth or soft leather strap (Diagram 11) which, passing around the elevated shoulder above, is buckled below to a belt which is kept down by straps secured to the

² Brit. Med., May 13, 1882.

³ Sanitary conditions and necessities of School Houses and School Life, p. 32, D. P. Lincoln, M.D.

American Public Health Association Prize Essay, 1886.

stockings. (2) Ordinarily, in light cases, the prevention of the raising of one shoulder will check the dropping of the other. If, however, it is not sufficient, a simple crutch can be employed in connection with the shoulder strap to the opposite shoulder.

Diagram II.

More easily carried about than a cushion is a thick pad of saddlers' felt, which can be worn (secured to the waistband and drawers under the skirts) on one buttock.

Diagram III.

Where the faulty attitude is one of leaning to the side, latent supports of some sort are of course needed. Corsets of some sort are most commonly used. Many different varieties are in vogue — plaster-of-Paris jackets and their substitutes, glue felt silicate of potash, leather made on molds taken from the jackets, and cloth corsets reinforced by steel. In choosing the proper corset one has to be guided not only by the medical conditions of the case, but by the circumstances of the patient, and the importance of sightliness and comfort, as well as of efficiency. The matter of personal custom of the surgeon often dictates the choice of the material employed. Leather corsets, formed by being stretched on molds of plaster jackets, the leather being reinforced by steel strips, will be found efficient and convenient. In light cases the leather corset need not completely encircle the trunk, but may simply be made in two lateral halves, connected by lacings or straps (Diagram IV).

The place on the corset for the reinforcement by

steel strips varies in a measure, in each case, but they should be so placed as to check the dropping of the shoulder if there is a tendency to this, as well as to check a habit of bending the spinal columns to one side. Lateral supports should be as low on the side of the pelvis as possible.

Corsets of this sort, or of any sort, are incapable of entirely preventing leaning to one side. They serve rather as checks or reminders. As a type of the stiffest corsets the plaster-of-Paris jacket may be taken. But it will be seen that although the trunk may be made straight by suspension, and a plaster jacket applied on a patient in this position, it is impossible to prevent a certain amount of slipping of the corset on the patient. If the corset slips upwards, or if the pelvis alters its position, the bearing of the corset on the pelvis is loosened, and the corset tips and is pressed to the side by the trunk (Diagram V).

This, of course, is true to a still greater degree if the corset is loosened or is made of less stiff materials as springs.

In order to prevent any tendency of the trunk to lean sideways, it is necessary that the base of the support be fixed. This can be done by the securing steel band and upright to the pelvis by means of straps resting on the crests of the ilia, and by furnishing perineal bands, and also by adding steel rods, which connected with the band by a rivet joint at the level of the trochanter, descend along the side of the thighs, and are secured to the thigh by straps. Flexion of the thigh is not prevented, but adduction or abduction of the thighs is possible to a very limited extent,

Fig. 1.

Fig. 2.

Fig. 3.

Diagram IV (3 figures).

and the tilting of the pelvis is therefore checked. (Diagram VI).

If the corset embracing the trunk is lashed to the upright of such an appliance, leaning to the side is prevented.

It will also be found an advantage if in place of the customary steel band encircling the pelvis an arched one be substituted which fits to the hollow of the back, and is not displaced by the movement of the pelvis incident to the motion of walking, or change from a standing to a sitting position.

If it is desirable to exert pressure upon the projecting ribs, levers moved by screw-power can be connected at one end to the steel support, as described, and furnished with paddles at the other.

The place for these arms necessarily varies in cases. In general, the place of pressure and counter-pressure will be designated in the accompanying diagram. (Diagram VI).

Diagram VI.

It is, of course, undesirable that pressure should be applied upon the hollow caused by sunken ribs, or that the chest be compressed. It is difficult, if not impossible, to prevent this if corsets alone are relied upon.

The criticism has been urged that pressure upon the ribs is useless, as pressure of the ribs which are connected with the spinal column by means of a movable articulation affects only the ribs, and not the twisted spine. This is certainly true in cases with

fixed curves with osseous change. It is not, however, entirely true in flexible curves, as can be demonstrated upon the cadaver and on patients.

It must, however, be frankly admitted that the amount gained by direct lateral pressure is not as great as has been expected.

Assuming that the chief cause of lateral curvature is the superincumbent weight, it is manifest that no corset can entirely meet the indication of removal of the primal cause.* Removal of the primary cause can only be done in two ways; namely, recumbency and suspension.

The objections to recumbency are evident. Lateral curvature is not an affection where a climax is reached in a few weeks or months. It is a matter dependent upon growth, occurring during the growing years, when the bones are in a forming state. To condemn a growing girl to years of confinement, as was formerly done, to a spinal couch because a shoulder projects, is extremely severe treatment, justifiable only in the certainty of the imminent peril of the patient, rarely true in scoliosis. Confinement to a spinal couch for a few weeks is, of course, useless. As a method of treatment, recumbency should be employed for a long time, if at all. It can, however, be used as an adjunct in suitable cases for the purpose of temporary correction of the deformity and daily rest for the spine.

That the mere matter of temporary rest to the back is of importance, when it is considered that the spinal column is the only means of the support of the weight of the upper part of the body; in other words, that the lower part of the column bears nearly constantly for twelve hours, even in a child of adolescent or comparatively small size, a downward pressure of forty to fifty pounds on a surface not two inches square.

In lighter cases, simple recumbency on the back, face, or one side for a few hours every day is sufficient; but in severer cases it is desirable to add some form of lateral pressure and suspension. Pressure can be furnished either by placing sand-bags under and upon the projecting deformity, requiring the patient to lie upon the back, or a more elaborate arrangement can be used, furnishing lateral pressure by means of straps and screws.

Extension to the head or of the lower extremities is of service in upper dorsal and in lumbar curves respectively, and can be readily attached to any of the arrangements of recumbent fixation.

Direct vertical suspension will correct flexible lateral curves, as it removes the chief cause; namely, superincumbent weight. It is, of course, impracticable to employ it continuously. It was originally supposed that the application of a plaster jacket to a patient suspended preserved the correction obtained by suspension, and a portable appliance, with the benefit of suspension, was thus furnished. Experience disproves such an idea. As has been seen, slipping of a corset alters the pressure so, that so far from corrective pressure being furnished by such a jacket, pressure upon the sunken ribs may take place from the twisted jacket. This will not be obviated by making the jacket more full over the concavity, for this enables the jacket to tilt still farther.

Curvatures which are fixed either by the adapted shortening of ligaments or by bony change will not be corrected by direct suspension.

Various appliances for twisting the spinal column

* Boston Medical and Surgical Journal, September 9, 1886, p. 221.

will be found of some help. The idea is an old one, but it has been improved by Lorenz and Beely.⁶ The arrangement depicted in the accompanying diagram (Diagram VII), which is slightly modified from the appliances described by them, will be found of service. Daily use of this will be found to correct distortions which simple suspension or recumbency will not correct. The effect of such correction is only temporary, unless the gain be improved upon by fixative appliances. This Lorenz reports to have done successfully. I cannot claim to have been equally successful, although the fault may be that I have not used it as persistently as Lorenz has done.

Diagram VII.

appears in a recumbent position, or when the patient is suspended, or with the arched back, is flexible. If it does not disappear, it is to be classed as fixed or resistant.

The patient's physical condition, whether anæmic or otherwise, the digestion, the nervous system, and the capacity for sleep, etc., are to be carefully noted. The rate of growth, whether normal or excessive, is estimated by a comparison with Bowditch's tables of height and weight, taking into account in each case the probable influence of heredity. The muscular strength is determined by means of dynamometers, the muscles to be investigated being those that hold the trunk in the normal position, grouped, not according to individual muscles, but according to function; that is, the muscles which hold the head up, the muscles which hold the scapula back, the muscles which hold the trunk erect. The range of sight is also to be noted, and any difference in the strength of either eye is to be taken into consideration.

The dependency of proper treatment on these facts can readily be understood if we consider that, if the patient's muscles are very weak, the employment of any jacket or appliance which would cramp the use of the muscles is necessarily to be avoided as far as possible, as the development of the muscles is the

chief curative measure; and, on the other hand, in patients with very strong muscles, and with faulty habits of position, if these habits can best be corrected by appliances temporarily worn, such measures are advisable. If the patient is constitutionally weak, needing sunshine and air, it is perfectly irrational to enforce recumbency; or, if the patient's nervous system is exhausted by rapid growth, it is a hygienic crime to allow forcing at school.

The chief objection to the use of appliances is a substantial one; namely, that they can never form a definite cure, in that they can never reach the root of the matter, and simply correcting a faulty position does not prevent a recurrence of the distortion on removal of the brace. It is, therefore, evident that, if mechanical means are to be used at all, they are simply to be used temporarily, while there is hope of the correction of the deformity or danger of increase; and that they should be subsidiary in position to measures which will enable the patient to hold himself as nearly in a proper position as possible.

To epitomize the treatment of lateral curvature is difficult, as it necessarily varies in different cases, but the following general line of treatment can be sketched: In fixed lateral curvature in adults, with marked osseous change, corrective treatment; that is, for the correction of the curve, is useless, and preventive treatment is, as a rule, unnecessary in persons of good health, but in certain cases with poor health, preventive treatment; that is, the prevention of the increase of the curve, is demanded.

In fixed and in flexible curves in young and in rapidly growing adolescents the preventive treatment is essential, and the corrective treatment is advisable in most cases; the importance of the latter varying, according to the amount of bone deformity. Preventive treatment should be primarily gymnastic or postural, mechanical treatment being either unnecessary, or used as an aid in the prevention of faulty position. Corrective treatment is either postural or mechanical, or better, a combination of both with gymnastics.

Many authorities claim that lateral curves are certain to increase. This, according to my experience, is by no means certain, as I have watched cases for some years where treatment was neglected, and the curves have remained essentially unchanged. The affection would seem, in a large majority of cases of healthy children, to be entirely self-limited in its character. In rapidly growing children, however, or in children physically weak, there is great danger of increase of the curve, and in some cases the increase is quite rapid.

A diminution of the curve in the process of growth, the "growing out" of the deformity, may be said never to take place. It must also be admitted that certain cases of lateral curvature are entirely beyond surgical remedy. Where the bones are much destroyed, it is as impossible to attempt any correction as it would be to correct the curve after caries of the spine. Such cases are capable only of palliative treatment, but can be made comfortable, and their symptoms relieved, by corsets, by massage and by certain gymnastics, by suspension and by recumbency.

REMARKS ON THE PLASMODIUM MALARÆ.¹

BY FREDERICK C. SHATTUCK, M.D.

THE suggestive paper of Dr. Whittier, entitled "The Malarial Influence on the Typhoid Fever of 1887 in Boston," read at a recent meeting of this society, and since published in the JOURNAL,² has made me think that the members of the Society may care to see some stained specimens of the plasmodium malaria, and listen to a few words as to the manner of looking for these bodies, with the precautions to be observed. I was so fortunate last summer as to have several cases of malarial infection at my wards at the Massachusetts Hospital, and in some of these my assistant and I had no difficulty in finding the organism which is thought to be the cause, as it certainly seems to be the concomitant of the paroxysms.

Laveran, who studied the disease in Algiers, was the first to describe the organisms to which the Italians, Marchiafava and Celli, working in and near Rome, gave the name plasmodium. Their results were in every way confirmatory of those of Laveran, as have been the results of other workers in the field, including among Americans Councilman³ of Baltimore, and Osler,⁴ of Philadelphia, to both of whom, particularly the latter, I wish to express my obligations. In the first place there is but little hope of detecting the organism in the mild intermittents originating in New England except during the paroxysm, or perhaps immediately before or after it. In the severer forms of chronic cases of the disease certain blood changes can often be detected, even when anti-periodics have been given.

A word is required as to the proper method of examining the blood. The finger-tip from which the blood is taken should be carefully washed and wiped dry, even from perspiration, that no extraneous dirt may get into the preparation. After pricking the finger a very small drop of blood is to be taken on a clean cover glass, which is then, in examining fresh specimens, to be applied to the slide, pressure being exerted upon the cover with the nail in order that the blood may be spread out in a thin layer. The corpuscles should be isolated, not sufficiently thickly aggregated to run into rouleaux. A specimen remains serviceable longer if the edge of the cover-glass is protected from the air by paraffine, and a warm stage is convenient; but neither one nor the other is necessary. No reagent is to be added.

If it be desired to preserve specimens a thin layer of blood is spread upon a cover-glass, thoroughly dried in the same manner as sputum in the search for tubercle bacilli, stained in methyl blue or fuchsine, and mounted in balsam. My friend, Dr. Osler, tells me that this staining process is very easy, but my efficient house-officer, Mr. N. F. Chandler, had very poor success with his attempts to stain slides taken from my patients. The slides which I show you were given me by Dr. Osler. All of our observations of the organisms were made upon the fresh specimens.

It is desirable to use high powers, though the bodies can be seen by one who knows what to look for with a power of five or six hundred diameters; but the changes which the bodies undergo are not so easily studied.

It is not my intention here to describe all the forms which have been observed. Those who are interested will find them all, with full reference to the literature of the subject, in Osler's paper. Some of these forms are associated chiefly with the inveterate and severe types of malaria such as we do not see here, except where now and then a case comes from a distance.

The forms seen by Mr. Chandler and myself were those which are most common and are found in the red corpuscle. To describe them I cannot do better than quote the words of Osler. "The attention of the observer will most likely be first attracted by the presence of a few dark grains in the stroma, and a careful study of a suitable specimen will soon lead to the conviction that these are not scattered loosely, but are enclosed in a finely granular or hyaline body in the interior of the corpuscle. The red disks in which they occur are usually large, look flat, and are very often paler than normal: they may, indeed, exist only as colorless shells. The number of corpuscles so affected varies extremely in different cases. In some instances they are readily found after a search of a moment or two, but, in other cases, a prolonged examination may be necessary. One is usually present in each corpuscle, but two or three, or even four, may occupy the stroma. They vary greatly in size, the smaller ones not occupying a fourth of the corpuscle, while the larger ones may almost fill it. A delicate contour line can usually be seen separating the body from the stroma; at times this is very indistinct, particularly if the illumination is very bright. The substance appears hyaline, or very finely granular, and the pigment grains are scattered irregularly in it. They may be very numerous, and give a dark aspect to the body, or they may be scanty. They frequently present rapid Brownian movements. Occasionally a vacuole may be seen in the interior of the body. In several instances the bodies appeared to be inclosed in a clear space — vacuole — in the stroma. When first seen they are more or less spherical, but, as already stated, the outline may be indistinct. The pigment granules may be seen to alter their position in relation to each other. If the margin of the body is carefully observed, slow changes can be seen, which gradually bring about alteration in shape. These movements, which appear to be amoeboid in character, can often be traced with great ease. Change in position of the body in the corpuscle result from them. They are decidedly slower than the amoeboid movements of the colorless corpuscles." Osler states that he has never seen any evidence of migration from the corpuscle; it was my fortune once to see the body escape from the red disk without destroying the latter.

Another intra-cellular form seen in one of my cases was the hyaline non-pigmented variety, the changes in which are more rapid than those in the first described pigmented form. What the relation of these forms to one another is — or is not — has not yet been determined. In this same case the rosette form was also seen within the cell, but its segmentation, as described by Osler, was not followed. The extra-cellular forms were not seen by us. The amoeboid movements continue for half an hour or more, at the ordinary summer temperature.

It remains to give a brief statement of my cases. Six malarial cases were admitted to my wards during my last service. Two of these had no paroxysm after entrance, though they received no treatment. There

¹ Read before the Boston Society for Medical Improvement, April 9, 1888.

³ Transactions of Association of American Physicians, Vol. I, p. 89.

⁴ British Med. Journal, 1887, March 12.

were consequently only four available for a study of the blood changes.

I. A Swede, contracted the disease five months ago while working on the Panama Canal, and suffered from chills nearly every day since. The day after entrance the organisms were found in pretty large numbers during the chill. The next chill was prevented by quinine and the organisms disappeared.

II. Contracted the disease in the West Indies three years ago. The patient had lately been in Mobile, and had a recurrence of chills which were somewhat irregular. The spleen was decidedly enlarged: the man's general condition was very poor. His blood was examined three times during the chills with negative results. He was cured by the hydrobromate of quinine under the skin, as the stomach rejected the remedy.

III. A woman, contracted the disease near Boston about a week before entrance: anticipating tertian, she had one chill in the hospital, the pigmented amœboid form was found; quinine, cure.

IV. Disease contracted in Wayland; tertian, pigmented amœboid form, quinine, cure.

Thus in three cases out of four the bodies were found without difficulty. Why they were not found in Case II, I cannot explain. The malarial history was clear, his spleen was enlarged, and he was promptly cured by quinine. Osler mentions some cases in which the plasmodium could not be found, but in most of these there was opportunity for only one examination. The far larger experience of Osler and Councilman shows great constancy and some obscure cases in which the diagnosis was made by the presence or absence of the bodies. Marchiafava and Celli succeeded in producing malarial paroxysms accompanied by the plasmodium in the blood, in previously healthy persons, by the injection of blood drawn from a malarial patient during the paroxysm. All attempts to cultivate the organism have thus far failed.

RECENT PROGRESS IN ANATOMY.

BY THOMAS DWIGHT, M.D.

THE CÆCUM.

TREVES's excellent lectures on the Intestines, published in 1885, contained, we believe, the first statement written in English that the cœcum is completely covered by peritoneum. It must not be forgotten, however, that new as this appeared to English and French readers, the Germans had known it long ago. It is surprising that if there is a substantial regularity of arrangement such absolutely opposite views should be held. Treves declares that he has never seen a cœcum with its posterior wall uncovered by peritoneum. M. Tuffier¹ has written a very careful paper on the anatomy, physiology and pathology of the cœcum, which is in the main, though not wholly, confirmatory of Treves's views. In a disputed question of this kind it is essential to define the limit of the cœcum, and we may accept Tuffier's statement that it coincides with a plane immediately above the ileo-cœcal valve. If a window is made in a dried and distended cœcum the upper limit is clear enough, but we must own that it is not easy to recognize it when the intestines are un-

opened and *in situ*, although Tuffier says it is indicated by *une forte bandelette annulaire du colon*. It must be admitted that if, as a ready method, we draw a line across the colon from opposite the highest point of junction of the ileum and call all below it cœcum, we give that part of the intestine all and more than belongs to it. It would be more just, but more difficult, to draw the line from a point at the middle of the end of the ileum.

M. Tuffier describes the lymphatic glands of the immediate neighborhood, which are so important that we give his description literally translated:

"The lymphatics of the anterior region represented in Heule, injected by M. Farabeuf, (specimen in the Musée Orfila) follow the anterior ileo-cœcal artery to empty into two glands, which I have constantly found in the superior ileo-cœcal fold, and which are very distinct in the child. The posterior lymphatic glands do not appear to me to have been figured nor well described by the authors. They are, however, constant and very well developed. To see these glands well it is enough to turn the cœcum over on to its anterior surface and examine the posterior one. They are then seen through the transparent peritoneum. They lie on the posterior and inner surface of the cœcum, of which they form a part. They are covered by the peritoneum, which at this level binds them to the walls of the intestine itself, and separates them completely from the iliac fossa. In general they form a group of from three to six, but one or two stray ones may be found in the neighborhood of this group."

The importance of this group is hardly likely to be over-estimated. We must refer the reader to Tuffier's paper for the account of the fossæ and peritoneal folds. Suffice it to say that following Treves's lead he has done much original work.

As to the peritoneal covering he found in 120 subjects, adults, children and fetuses, that in 9 only the superior posterior third of the cœcum was uncovered by peritoneum. These nine were all adults or old people. The height at which the peritoneum leaves the posterior surface of the gut varies greatly. In most cases it is a finger's breadth above the ileo-cœcal opening. Tuffier has twice seen the entire ascending colon completely covered and as free as the cœcum.

The writer of this report would state in this connection that, having given particular attention to this point of anatomy, he is convinced that the German teaching which Treves has followed, namely, that the cœcum has a complete peritoneal covering, is undoubtedly correct in the great majority of cases. Treves goes too far, however, in looking on it as probably constant, for exceptions sometimes occur. The writer, moreover, in examining the bodies of thirteen infants who died at, or shortly after birth, has found in two cases the posterior surface, and in one case the upper third of this surface, without peritoneal covering.

Our author calls attention to another point, which we believe has been but little noticed, namely, the degree of firmness with which the peritoneum is attached to the other coats of the intestine. In the colon the attachment is lax, so that the serous layers can be moved, but in most parts of the cœcum the layers are firmly joined so the peritoneum cannot be peeled off without tearing. It is loosely attached, however, in the upper posterior third.

SUSPENSORY LIGAMENTS OF THE THYROID GLAND.²

Mr. James Berry made a communication on this subject at the July meeting of the Anatomical Society of Great Britain and Ireland. These ligaments, blending with the capsule of the thyroid, attach it to the cricoid on either side, forming a kind of sling. Though strong, they have no very precise borders, blending, as they do, with the fascia on either side. When the gland is enlarged these ligaments become strong bands, mooring it to the larynx. Mr. Berry looks on them as of much surgical importance, as they are obstacles to the removal of the thyroid, and it is to be noted that they lie directly below the recurrent laryngeal nerves.

CHANGES IN SHAPE OF THE LIVER.³

Mr. Symington has shown by frozen sections that both the position and shape of the liver vary with the condition of the stomach. Without going so far as those who maintain that the liver has no definite shape of its own, many have believed that when healthy its shape is very changeable. We think, however, that few of these would have been prepared for such remarkable shapes as are shown in some of Mr. Symington's figures. When the stomach is distended the vertical diameter of the right lobe of the liver is greatly increased, and the transverse diameter of the entire organ much diminished. Moreover, according to Mr. Symington, the distension of the stomach causes a certain rotation of the liver on a vertical axis passing through the inferior vena cava. In some cases Mr. Symington has taken the slices of frozen liver out of the sections, and, putting them together, has reconstructed the organ so that it could be drawn as a whole. It may be objected that frozen sections cannot show that the liver actually changes either shape or position, and that before they can give anything amounting to a demonstration, a greater number of observations is required. This can hardly be disputed, but it may be said that the results are so much in accord with what might be expected (except that they are unexpectedly striking), that it is unlikely that further observations will do more than modify matters of detail.

VALVES IN THE GASTRIC AND OMENTAL VEINS.⁴

It is taught as established that there are no valves in the portal system of man. Sappey, to be sure, found some in the very small veins in the falciform ligament of the liver that connect the portal system with the veins of the abdominal walls, and Bauer has described them in the short veins of the stomach, but Cruveilhier, who quotes him, failed to confirm his statement. With these exceptions, nothing, so far as we know, has been written on the subject. Dr. Hochstetter recently came across valves on injecting the portal system of the body of a child a few months old, and was led to make many examinations. He found that in the infant the tributaries of the right and left gastro-epiploic veins, which form an arch along the greater curvature of the stomach, both those from the stomach and from the omentum, had sufficient valves at or near their points of entrance. The veins open-

ing into the coronary vein, which runs along the lesser curvature of the stomach, are occasionally found with valves, but without regularity, excepting in the case of the branch (and its tributaries) nearest the œsophagus. The veins of the omentum, however, have valves not only at their entrance into the gastro-epiploic veins, but throughout their course, wherever a smaller branch opens into a larger. These valves are as well formed as those in other veins, but are delicate and tear comparatively easily. With increasing age they become insufficient: first, the gastric branches of the right gastro-epiploic near the pylorus; next, those emptying into the left vein of the same name; then those of the short gastric veins. By the twentieth year, apparently, there remain no valves in working order along the greater curvature. The valves of the highest branch of the coronary vein endure comparatively long, and those of the omentum longer still. Hochstetter has found perfect valves in the omentum in old persons.

It was known that in some mammals valves are present in the portal system, but Hochstetter has added much to our knowledge of this subject. He has shown that valves are to be found in the gastric and splenic parts of the portal system in many mammals, but that their importance varies greatly. He found them in some carnivora, especially the dog and cat, to have a real, and apparently permanent, influence on the circulation; in some orders he found that as in man, they have only a temporary function, and again, sometimes, as in the rabbit, there are merely traces of valves. They may, therefore, in some cases be considered rudimentary organs.

Another paper by Dr. Karl Klotz⁵ shows that many valves become useless in the course of life. He examined the long saphenous vein and its tributaries in seven adults, two new born infants and one fœtus. The number of observations is extremely small, but they show tolerably well the atrophy of the valves which is, we think, the most important point of the paper. Thus in the two infants and the fœtus all the valves were in good working order, but in a man of twenty-five, 17% were impaired. In two others of about thirty, and in one of forty-two, the proportion was about the same, but in a man of forty-eight it had increased to 29%, in one of fifty-four to 40%, and finally in an old man of seventy to 81%. That many valves should become useless in old age is not surprising, but what is remarkable is the fact that about one-sixth should be impaired before twenty-five.

VEINS ON THE PHARYNX.

Messrs. Bimar and Lapeyre⁶ describe a remarkable subinuous venous plexus in the lower part of the pharynx at its posterior aspect. It is found at all ages and is not more developed in the old than in the young. It communicates with the superficial pharyngeal plexus by several systems of veins that perforate the inferior constrictor. Of these the following are nearly constant: (1) A superior and posterior one near the median line. (2) One running upward and outward parallel to the posterior border of the thyroid cartilage and forming a part of the origin of the pharyngeal vein. (3) One passing outward towards the thyroid body, and emptying into branches of the superior thyroid vein.

THE INTERARTICULAR FIBRO-CARTILAGE OF THE STERNO-CLAVICULAR JOINT.

M. Poirier,⁷ having met three times with absence of the fibro-cartilage, has undertaken the study of its use and significance. He regards the usual view that it practically establishes a correspondence between two surfaces that do not fit as erroneous. He maintains that, though the articular surfaces of the sternum and clavicle vary, still they do correspond. Having dissected a hundred joints, he finds that the articular surface of the clavicle which encroaches on the lower surface of the bone is distinctly convex vertically, and slightly concave from before backwards, and that the sterno-chondral joint is distinctly concave in the former direction, and very slightly convex in the latter. He then points out that the interarticular cartilage is very variable in shape, and concludes that it is present merely as a rudimentary structure, the representative of the interclavicle. We are not inclined to dispute the homology, but we think Poirier in error not to recognize that the cartilage adds very much to the security of a very important joint, the only one, in fact, between the trunk and the upper extremity.

ANASTOMOSES OF THE NERVES OF THE ARM AND HAND.

M. Henri Hartmann,⁸ at the beginning of an important communication to the Société Anatomique, alluded to a previous one, in which he had shown that the collateral nerves of the fingers were very frequently perforated in the palm of the hand by the digital arteries. This occurred in two ways: either the vessel passed through a small opening, a "button-hole" in the nerve; or else the fibres of the nerve, separating into different bundles, left a long elliptical space, through which the artery made its way. It is a rather curious fact that the branches of the median nerve should show the button-hole, and those of the ulnar the elliptical opening. It appears that it was suggested that M. Hartmann had struck a series of uncommon cases, to which he says that he had found these appearances in sixteen hands out of twenty-four, and that having continued his investigations, he has found in twenty-nine of forty-five hands either the button-hole or the ellipse on one or another of the digital nerves. He has noticed several times an arrangement in which the opening was made not by a splitting of a nerve, but by fibres from the next branch of the parent nerve rejoining the nerve in question. If the reader should not find this clear let him imagine a Y, the arms of which represent two digital nerves. Let him then imagine that certain fibres begin by following one arm for a short distance, and then leave it to join the other, thus forming an opening bounded above by the bifurcation. Hartmann points out that in this case no dissection is necessary to separate the fibres, which only lie against the bundle; they appear to have joined inadvertently, without really mingling with them. He then goes on to describe analogous cases in the large nerves of the arm, in which the fibres of a certain nerve apparently join another and then leave it. This appears to occur most frequently between the median and the external cutaneous, the fibres coming sometimes from one, sometimes from the other. We should say that more than twenty years ago a branch of the musculo-spiral was described by Kranske, running

along with the ulnar, and leaving it near the elbow. Hartmann describes also long ellipses made by fibres rejoining their own nerve after a long course.

The special importance of these observations lies in their bearing on certain clinical facts which are hardly to be reconciled with the teachings of anatomy and physiology. We refer to the well-known fact that the paralyses of motion and sensation after section of a nerve do not always correspond with the area of its distribution, and that sometimes the discrepancy is very striking. Richet reported an extraordinary case,⁹ in which, after section of the median, insensibility was unchanged, except that it was diminished on the palmar surface of the second and third phalanges of the index, and there are other cases in which motion has persisted. We must admit that we find it difficult to account for extraordinary cases by the theory that when a certain nerve is cut, and but a part of the usual effect follows, this is due to the fact that many of its fibres have taken another course; but this theory will do well enough for cases where the discrepancy between the actual and the expected result is not great.

Clinical Memoranda.

NEPHRECTOMY OF THE RIGHT KIDNEY FOR CHRONIC ABSCESS.¹

BY JOHN HOMANS, M.D.

The subject of this operation was an intelligent girl twenty-four years old, a patient of Dr. C. B. Belt. Her illness dated back three years, when she began to have urinary symptoms, as shown by frequent micturition. In July, 1887, there was some fulness in the right lumbar and iliac regions, and in August a tumor was discovered, which has slowly increased in size. During the last three years she has lost much flesh and strength, and now feels weak and tired. The catamenia have been absent for six months. Her appetite is now good, and her pulse 116 per minute, and of fair strength. She has almost complete incontinence of urine. The urine is yellow, alkaline and offensive. One-half per cent. of albumen is present, and a trace of sugar. The coloring matters are diminished. Specific gravity, 1028. Sediment thick and heavy, consisting of pus, a few blood globules, epithelial cells from the bladder and kidney, crystals of triple phosphate and uric acid. There is a tumor about four inches long, of an oval shape, in the right loin. This is movable, and extends from below the short ribs towards the umbilicus, and then turns outwards to within two inches of the crest of the ilium. Pressure on the loin is transmitted to the tumor, which is apparently the right kidney much enlarged. Dr. Belt and I agreed that an attempt should be made to drain the kidney before resorting to an operation for its removal, and the patient was admitted to St. Margaret's Home. On the sixth of March I made an incision over the tumor in the right loin and exposed the kidney, which I punctured with an aspirating needle. Thick pus was drawn out. The opening was then enlarged with the knife and the finger, and about three drachms of thick pus were removed. The size of the kidney, however, was not materially diminished, and

¹ Read before the Boston Society for Medical Improvement, April 9, 1888.⁹ Oazette des Hôpitaux, 1867.⁷ Bulletins de la Société Anatomique de Paris, 1888. Janvier.⁸ Bulletins de la Société Anatomique de Paris, 1888. Février.

it was impossible to enter other cavities where the same material would probably have been found. The kidney was sewed to the skin, and a large drainage tube was secured in its substance, and the cavity I had opened was syringed out. A Sims's catheter was kept in the bladder for a few days, and after that the patient gained control of her urine. For four weeks the cavity in the kidney was irrigated, but the evening temperature ranged from 102° to $104\frac{1}{2}^{\circ}$. It became evident that removal of the kidney was the only measure that promised any relief, and this was done on April 4. You will see by the chart what a relief this was.

An incision was made in the right loin extending from the twelfth rib to the crest of the ilium, nearly parallel with the external border of the quadratus lumborum. The peritoneum was not opened, the kidney was pulled out without very much difficulty, and the ureter, which was the only tense attachment, was secured, divided, and sewn to the skin in the lower angle of the wound. The vessels were then tied securely *en masse*, and the kidney cut away. A large rubber drainage-tube was inserted, and the cavity left by the removal of the kidney was cleansed with a solution of corrosive sublimate. The wound was sewn up and powdered with iodoform, and dressed with iodoform gauze. In the evening the temperature was 101° , the lowest evening temperature for weeks. On April 5th the temperature became subnormal in the morning, and then kept at about 99° morning and evening in the succeeding days. Up to this present time the patient has been doing well. About eighteen ounces of urine are secreted daily, and although there is not much improvement in the character of the urine, yet as we have got rid of one focus of pus, we may hope for an improvement in time. You will see that the kidney removed is about five and a-half inches long by two inches thick, and it weighed before being cut open seventeen ounces.

The cones have become converted into cavities of the size of a thimble and larger, and containing much thick, offensive, putty-like pus; the calices and pelvis are likewise filled with it. Even the forcible stream from a water-faucet will not wash away all the adherent pus.

The following are the chief points of pathological interests resulting from Dr. W. F. Whitney's examination of the kidney:

Somewhat enlarged; weight seventeen ounces; length, five inches. On section the parenchyma of the organ was largely replaced by cavities filled with a thick pus, communicating with the pelvis, the lining of which was thickened. The substance of the kidney that remained was firm, somewhat translucent. Microscopic examination showed this last to be composed almost entirely of fibrous tissue, in which were to be detected the remnants of tube and malpighian bodies. The kidney is one of chronic suppurative pyelo-nephritis. The search for tubercle bacilli was negative.

NOTE, April 28th.—Although the constitutional relief as shown by the fall of the temperature and pulse was satisfactory, the condition of the urine was not so; there continued to be about the same amount of pus as there was before the kidney had been removed. The appetite gradually failed and the patient died of exhaustion on April 14th. No autopsy could be obtained. Probably the other kidney was diseased as well as other organs. I think, however, that the course pursued in this case was consistent with the rational and sound practice of surgery.

J. H.

OVARIOTOMY IN A PATIENT EIGHTY-TWO YEARS AND FOUR MONTHS OF AGE.¹

BY JOHN HOMANS, M.D., BOSTON.

A LADY of the age above mentioned was referred to me through the kindness of Dr. Charles A. Dewey, of Rochester, N. Y. The patient was a widow, and had been the mother of five children, the youngest being forty-three years of age. On examination, I found a tumor of the left ovary, apparently without adhesions, in an active, healthy woman. The presence of the tumor had been known for about two years, and it had grown rapidly during the last six months. The lady said that if the tumor was likely to render the remainder of her life uncomfortable, she would like to have it removed.

On January 28, 1888, I removed the cyst, which proved to be one of the left ovary, somewhat multilocular and papillomatous. The fluid weighed thirteen pounds, and the solid portions one and three-quarter pounds.

On the sixth day the temperature rose to 100.5° , but subsided the next day, and the patient went home on March 2d. The oldest women on whom I had previously operated were each seventy-three years of age—one on November 19, 1881, and the other on December 26, 1883. Both of these ladies are now living in good health. Sir Spencer Wells's oldest case was seventy-one, and Dr. Keith's seventy-three. Mr. E. Matthews Owens, of Australia, has just operated successfully on a patient seventy-nine years and ten months of age. I could find no case as old as eighty years, but to make assurance doubly sure, I communicated with Dr. J. S. Billings, at Washington, and at his request Dr. Lörini made a thorough search, without finding any case recorded older than seventy-eight years of age.

WASHINGTON, March 16, 1888.

DEAR DOCTOR: Some days since, Dr. J. S. Billings handed me a letter with the request to look up the subject of ovariectomy in women of eighty years and over. Through the kindness of Dr. Robert Fletcher, I have been enabled

¹ Believed to be the oldest case on record.

to see the cards of the unpublished catalogues, numbering several thousand. I have looked up all the statistical tables obtainable, and consulted all the works on the subject in all languages, including Russian, Swedish, Hungarian, etc.; in a word, I have been over the subject most carefully, and have failed to find a single case recorded in any journal, pamphlet, or book.

I found quite a number of cases where the operation was done in women of seventy years and over; the oldest cases being two reported in Italy in women seventy-five years of age, and one in Russia, seventy-eight years of age. The result is a disappointing one to the seeker, but it will probably be satisfactory to the gentleman who ordered the work done. Yours very truly,

(Signed) R. LORINI.

It will be seen from the above that not a single case of ovariectomy in women eighty years of age or older has ever been reported, if Dr. Lorini's search has been exhaustive, and I think we may consider it so.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

APRIL 9, 1888. DR. FRANCIS MINOT, President pro tem.

A LARGE SEQUESTERUM FROM THE TEMPORAL BONE.

DR. BRADFORD, presenting a patient, said: This is a case of caries of the temporal bone following disease of the ear. The patient was at the Children's Hospital. Dr. Morse was kind enough to see the patient with me, and we examined with a probe. The child was in a very marked degree of emaciation, and had a marked facial paralysis, with a large swelling on the cheek, as you will see. Dr. Morse examined it, and he found a mass of dead bone around the external ear. He thought the sequestrum was not loose, and advised waiting. About a month afterward, as the patient became very offensive indeed, I cut down again and removed a piece of bone. The bone was loose and I succeeded in getting it out, and I can mark on the skull here what was removed. It came as a sequestrum. It ran from the mastoid process, which, of course, is not developed in the child, up as far as nearly to the top of the squamous portion. It reached down in front to the articulation of the jaw. Inside, the depression for the lateral sinus could be seen, and also the depression for the internal carotid. It required no particular force to remove it, but a certain amount of careful manipulation was needed. There was no bleeding to speak of, and the patient has improved very much since then. There is a discharge from the other ear, and the child is entirely deaf.

There was a caries of the metacarpal bone which is improving. There is tuberculosis of the skin, and there is still slight swelling of the face. A piece of bone came out from the wound a short time ago, and I think there is still a small portion of dead bone, which I didn't completely remove. The child has doubled in weight, and has a voracious appetite now, and will recover entirely; of course, with a total deafness. I show the case because I think it is a very large sequestrum to have

been able to remove. There is very little to be seen now, except the depression.

PERMANGANATE OF POTASH IN RATTLESNAKE BITE.

DR. F. GORDON MORRILL said: I had an opportunity, about six weeks ago, of seeing the effect of the injection of permanganate of potash on a dog which was bitten by a large rattlesnake—that is, if there was any effect. I don't think there was. The snake struck the dog at 3.13, p.m. At 3.16 three grains of permanganate, dissolved in sixty minims of distilled water were injected in the track of the fang, and around its immediate vicinity.

Both sphincters were relaxed, probably from fright, shortly after the puppy was struck. The dog was about ten weeks old. Ten minutes after the injection it ceased struggling, but had no convulsions.

At 3.30 the pulse was 200; at 3.35, 220; at 3.40, 130; at 3.45, 148; at 3.50, 150; at 3.52, 150, and very weak. An instant afterward he died. At 3.45 the respiration was gasping, and it remained so until he died.

This single instance only proves that permanganate of potash, however promptly injected, does not always save the dog. A number of gentlemen who have shot in St. Augustine during the last few years have lost valuable dogs. A gentleman lost a very nice setter last winter. Last winter he had a dog struck, and injected ammonia, and the dog got well. This winter he had another dog struck, and injected the ammonia, and the dog died very shortly after the injection. He didn't inject the ammonia in the track of the wound, but it was injected anywhere.

DR. E. H. BRADFORD read a paper on

THE TREATMENT OF LATERAL CURVATURE.¹

DR. ABNER POST said: I have been exceedingly interested in the remarks of Dr. Bradford; and I am sorry that I have almost nothing to say. Nobody could expect me to add anything to what Dr. Bradford has said. During my experience at the Children's Hospital I came in contact with a very large number of cases of lateral curvature, and there was one thing that I succeeded in learning most decidedly, what I suppose we all knew before, the fact that they were most singularly difficult cases to manage. And Dr. Bradford has emphasized to-night the one fact in regard to them that I think we all should remember, that they cannot be treated as a class; that they cannot be measured and fitted for a brace as they would be for shoes; but that, in order to gain any real benefit from treatment, they must be followed up carefully and conscientiously, and the treatment must be adapted to each individual case. I think we all ought to be thankful to Dr. Bradford for emphasizing just that one fact as he has so clearly to us.

DR. H. W. CUSHING said: I can corroborate, in almost every particular, what Dr. Bradford has said. One who has not come in contact with these cases can hardly realize the apparent hopelessness of any method of treatment, especially in these fixed forms, and I think that unless one has been so situated, he cannot fully appreciate the value of the work Dr. Bradford has done during the past few years, or the amount of time and labor such an investigation necessitates. As has already been suggested, one point

¹ See page 445 of the Journal.

should be emphasized in regard to the treatment of these cases; namely, the importance of a full appreciation of their etiology and pathology.

Superincumbent weight is now quite generally accepted as the chief predisposing cause. The active cause is "faulty attitude" resulting from

(1) Diminished power of the dorsal muscles; for example, rapid growth, rachitis, etc.

(2) Contraction from emphysema or caries of the transverse processes of the vertebrae (a rare occurrence.)

(3) Tilting of the pelvis from any cause, either traumatic or pathological.

The results of such attitudes is a deviation in a lateral direction of the spine accompanied sooner or later by rotation in its vertical axis. A recognition of the individual causes producing these variations is exceedingly important in the selection of the course of treatment to which the subject is to be subjected. That is, the first thing to be decided is whether the curve is a so-called flexible curve, as represented by the first two sets of cases spoken of by Dr. Bradford, or whether it is a fixed curve, in which there is a distinct osseous change. The principles of treatment governing these are, that we shall first remove the superincumbent weight, which has been attempted by the recumbent position, and in a majority of cases, especially in adults, is hardly practicable; or by suspension, which as a rule, is merely an accessory to other methods of treatment. The remaining treatment consists first, in correcting the deformity, and second, in preventing its recurrence.

In flexible cases, for example, those frequently seen in children, where there has been an exceedingly rapid growth, or where they are due to the patients being habituated to certain positions by occupation or modes of life. For instance, a young person accustomed to carry a heavy child thus continually assumes a "faulty attitude." These are the cases that are especially benefited by postural treatment and by gymnastics. In the other class, where the deformity has become more fixed, these methods (simple posture and gymnastics) are to be reinforced by other means, and to this class of cases, this apparatus of Dr. Bradford seems to be especially adapted.

It certainly is a great improvement over the older apparatus, where the appliances consisted mainly of plaster jackets or fixed supports of a similar nature. It certainly is an apparatus which is a particularly national one, as it fulfils the exact indication which the pathology of the deformity demands. As Dr. Bradford says, the old "fixed curve," where there has been a distinct osseous change, cannot at present be affected by treatment. Some other methods of treatment have been tried, which, in a certain number of cases, have caused a partial success. I think Dr. Bradford alluded to one, where the patient wears a raised shoe. Also, the method of Lorenz has caused improvement in a certain class of cases.

Perhaps it will be possible, if this line of investigation is carried out more fully, to eventually obtain some means by which these fixed curves also may be relieved. The various forms of talipes formerly considered as wholly incurable, are now treated with surprising success, and perhaps in the same way, by methods of treatment as thus suggested, these lateral curves, now the most difficult problem in orthopedic surgery, may be as successfully manipulated.

DR. JOHN HOMANS showed

AN EXTIRPATED KIDNEY.*

DR. F. C. SHATTUCK showed the

PLASMODIUM MALARIE.†

DR. F. C. MORRILL said: There is one fact which the Society may not be familiar with, that in all Southern cities there is an ordinance against turning over the ground in summer. They don't allow the ground to be turned over during certain months, or, if they do, they throw lime upon each spadeful of earth that is thrown up. In that way, they suppose that they prevent the occurrence of malaria in the neighborhood.

DR. FRANCIS MINOT: There is no doubt about the occurrence in the freshly turned up dirt. New streets which are put through in some place, are filled with malaria.

DR. MORRILL: They don't use the lime there.

DR. MINOT: It is impossible, in so great an undertaking. The workmen suffer very much, and also the people in the neighborhood.

THE SEVENTH CONGRESS OF INTERNAL MEDICINE HELD AT WIESBADEN, GERMANY, APRIL 9-12, 1888.

THE DISCUSSION ON ALCOHOL AS A THERAPEUTIC REMEDY.

DR. C. BINZ, of Bonn, Referee said: From remote antiquity, alcohol, or wine, has been regarded as medicinal. The Middle Ages called spirit of wine, *aqua vitæ*, *aqua juventutis*, *eau de vie*, *eau de jeunesse*, etc. In the seventeenth and eighteenth centuries, alcohol was recommended in febrile states. Still later and in our own day, as many of us well remember, its therapeutic use went out of fashion, and it was considered almost an indictable offence to prescribe even champagne for the sick. As late as 1865, Carl Otto Weber, our eminent surgeon, in a popular treatise denounced the use of wine in fevers.

The reaction against this extreme view commenced in England, and went so far, that even to-day we are obliged to sound the note of caution against the abuse of alcohol as a therapeutic agent.

Alcohol possesses three properties of which we avail ourselves in therapeutics; it is an excitant, an aliment and an antipyretic.

(1) The excitant action of alcohol cannot be called in question. After the experiments of Claude Bernard, those of Parkes have proved that moderate doses of alcohol under the form of cognac, Bordeaux wine, etc., raise the action of the left ventricle. Experiments made in my laboratory have given absolute confirmation to this view; small doses raise the blood-pressure, large doses lower it. The activity of respiration is also enhanced by alcohol in small doses. Zuntz has found an average augmentation of 9 %, my assistant a mean of 7 %, and with good sparkling Rhine wine, 15 % even. This increase, observed in the healthy man, is probably much greater still in patients in collapse.

Experiments oblige us to admit in theory that alco-

* See page 453 of the Journal.

† See page 450 of the Journal.

hol produces a retardation of digestion. But I believe that the quantity administered plays here a preponderant rôle, for we find in practice that alcohol is remedial in slight gastric ailments.

(2) The nutritive quality of alcohol cannot be constituted by any property which it possesses of tissue reparation; it is a respiratory aliment. The nutritive value of alcohol, is, however, indisputable. Alcohol does not (as has been affirmed) pass through the organism without undergoing any alteration. It does not leave the economy in its totality and unchanged. My experiments have shown that only 2.9 % of alcohol administered to a healthy man is eliminated as alcohol; 1.17 % is excreted by the kidneys; 1.60 % by the lungs; 0.14 % by the skin; all the rest, that is, 97.9 % is burned in the organism. Now the production of heat is a vital condition. A quart of good Rhine wine produces as much heat, that is, possesses as much respiratory nutritive value, as five or six tablespoonfuls of good oil, and is easier of assimilation.

The experiments of Zuntz and Goepfert prove that moderate doses of alcohol hardly modify at all in a healthy man the absorption of oxygen, and carbonic acid production. The alcohol, then, has simply produced an augmentation of heat. These medium doses economize force and matter, because they diminish from 6 to 7 % the decomposition of albumen. It is true that large doses accelerate the decomposition of this proximate principle (and this is an argument for moderation); and it is also true that the organism under disease obeys other conditions than the organism in a state of health, and patients in prostration or collapse can ingest large quantities of alcoholic stimulants without manifesting any symptoms of acute intoxication. Moreover, alcohol, when exhibited for therapeutic purposes, is given in small doses frequently repeated.

(3) I have mentioned as the third property of alcohol that of lowering the temperature. This may seem paradoxical, as alcohol is popularly said to be "heating," but just here there is a little confusion. Alcohol produces a feeling of comfort. It dilates the vessels of the stomach and skin. This dilatation is perceived under the form of heat, and this is the reason why alcohol is called "heating." I have collected 126 thermometrical observations, and have found that alcohol in small quantity exercises no influence on the temperature of the healthy adult; that medium quantities lower the temperature from 0.3° to 0.6°, and that large quantities produce a fall of several degrees during several hours.

One of my experiments was to produce an intense fever in two dogs by the injection of putrid substances. One of these dogs was treated by alcohol, while the other was left without treatment. In the dog that was dosed with alcohol the temperature fell from 40.6° to 39°. As soon as the temperature rose again alcohol was again administered with the same effect. Finally the dog got well. The other dog that got no alcohol died of putrid intoxication.

An advantage which is not to be lightly thought of in practice is that alcohol may be administered under different forms.

In order well to define our position as physicians in our relation to the temperance and prohibition societies, I would express myself thus: All that I have said pertains to the sick. The healthy man has no

need of alcohol, and if he indulges in ardent spirits he does this solely for his own pleasure and at his own risk. I place alongside of the whiskey nuisance the beer nuisance. The habit of taking alcoholic stimulants apart from meals is a public evil, from a sanitary, economic and intellectual point of view. The inveterate beer drinker is as much under the dominion of alcohol as the brandy drinker, and the greater sinner of the two.

DR. VON JAKSCH, of Gratz, Co-referee, continued the discussion: Dr. Binz has considered the qualities of alcohol from a physiological point of view; I shall speak only of its therapeutic applications. I have endeavored, in order more fully to understand its real value as a medicine, to apply the tests of clinical experimentation by giving alcohol under the form of wine or cognac, and with due precautions, to persons not accustomed to the use of alcoholic stimulants, as children.

Small quantities of alcoholic beverages (one to three grammes) produce in children, first, a diminution in the pulse. This is followed immediately by an augmentation; the pulse is not only quickened, but strengthened. Must we conclude from this that we are justified in utilizing this excitant quality of alcohol in all diseases without distinction? Assuredly not. It is *weakness of the heart* in affections accompanied by intense febrile manifestations that calls for alcohol; in cases of collapse and traumatic hemorrhages (as in puerperal women), alcohol often saves life.

As for the second quality of alcohol, its nutritive value, the opinions of physiologists may differ, but to the sick person this quality is a settled fact, and the clinical observer has no doubts regarding it. Thus far, experiments have been largely made on healthy adult individuals more or less accustomed to alcohol; this is why I have undertaken similar experiments with sick children. The result has always been a notable diminution in the quantity of urea excreted.

As for the special applications of alcohol, its use in diphtheria, recommended as far back as 1806 by Jastus, seems to me to be underrated. I cannot say that alcohol is a specific in diphtheria, but this agent, administered in large doses at the onset of the disease, seems to me to constitute the best treatment of this affection.

In typhoid fever, by the side of cold baths, alcohol has a great value. It acts as an excitant and as a food. The functions are raised, and the patients feel better. But precisely in these cases, where Stokes was the first to recommend alcohol in 1839, a frightful abuse has been made of this agent, and I need only instance that English physician whose patient consumed during an attack of typhoid fever twenty-one quarts of brandy and twenty-four bottles of champagne. By such treatment you can doubtless cure typhoid fever, but you are almost certain to make your patient an inebriate.

In septic poisoning, alcohol is *par excellence* the remedy, and simply indispensable.

The last quality of alcohol, its antipyretic action, has been proved by the clinical experimentation of Riegel, of Giessen. But I do not make much account of this quality, all the non-specific antipyretics having little value clinically.

As for the influence of alcohol (when administered with therapeutic intent, be it understood) on diges-

tion, it certainly does not impair this function, while, at the same time, this influence can hardly be favorable, except in cases which present no grave anatomical alterations of the digestive passages.

Alcohol possesses still a hypnotic action which does not manifest itself in feverish patients, but in the neurasthenic. It is true that in recommending it for such patients we must use special precautions, and take into account individual temperaments and idiosyncrasies. Beer acts better as a hypnotic; I cannot say whether this effect is due to the alcohol alone, or in part to other elements which enter into the composition of beer.

As for the form under which to administer alcohol, I would say that when you wish to avail yourself of its excitant quality, you should employ the stronger (distilled) liquors; when you wish to utilize its nutritive quality, you should give the light (white or red wines; when you desire a hypnotic effect, it is to beer that you should give the preference.

DR. W. H. ERB, of Heidelberg: Alcohol is doubtless a therapeutic remedy which nobody would wish to be deprived of, but the contraindications should be well understood. The gentlemen who have just spoken have told you of the immediate effects of alcohol, but there is still another, a secondary effect, the depressant effect, commonly experienced the morning after copious libations. Is it possible that this effect is not felt also by patients to whom alcohol has been freely administered, especially by those who are little, if at all, used to stimulants, such as women and children? It seems to me very necessary to have in mind this possibility.

When a powerful stimulation is indicated, instead of alcohol alone, I prefer alcohol associated with some other stimulants, as musk and camphor.

Another question presents itself to my mind — may not alcohol be deleterious in certain diseases by irritating the organs concerned, in its elimination (the lung in cases of pneumonia, the kidneys in nephritis)? Observations are wanting on this point; but it is well to call the attention of practitioners to it.

The unhappy consequences of the prolonged usage of ardent spirits by well persons may also be experienced when alcohol is given with therapeutic intent. I need only remind you of instances of the kind sometimes occurring in phthisis. In giving utterance to these few remarks, I do not wish to be misunderstood. I am not an opponent of alcohol, but prescribe it often.

DR. MERKEL, of Nuremberg: In pneumonia, alcohol has given me good results, especially in averting asthenia and collapse; its prolonged use, however, seems to me detrimental. I fear that our young practitioners are inclined to give too large quantities of alcoholic stimulants at the onset of diseases, little care, choice or judgment being exercised. It would be well if clinical teachers would put their pupils on their guard against this abuse.

DR. H. NOTHNAGEL, of Jena: I have heard the appeal to clinicians against the abuses of alcohol. But what remedy is there which does not give occasion to abuses? Has this not been the case with electrotherapy, hydrotherapy, iodide of potassium, antipyrine, etc., which have each and severally been administered for all affections imaginable?

Permit me to point out a different kind of abuse, which cannot be too strongly condemned; I refer to

the habit of giving wine or beer to children. In certain classes of society, children from two years old and upward, are regularly dosed with these liquors. This practice is an abominable one. The healthy child has no need of excitants, and the habit which I am denouncing destroys, or at least enfeebles, for a whole lifetime the nervous resistance of the organism.

DR. T. JUERGENSEN, of Tübingen: Perhaps the reproach of Dr. Merkel is made in part to me, since for twenty years or more I have made use of wine as a remedy. In basing myself on this experience, I think that I can answer Dr. Erb's questions. The secondary depressing effects which make themselves felt in the well man — do they also exist in the feverish person? I believe myself warranted in saying no. Moreover, I have never seen any irritation of the organs by which alcohol is eliminated; we must not forget, also, that it passes out of the body in a very dilute state. Lastly, chronic alcoholism does not follow the therapeutic usage of alcohol by fever patients, who are generally only to glad to give up the use of spirits when allowed to do so.

DR. RUCHLE, of Bonn: I have also observed certain deplorable effects from the administration of alcohol in acute diseases; for example, acute alcoholic delirium in cases of pneumonia. In chronic affections of the myocardium, alcohol is serviceable along with digitalis, in maintaining the vigor of the heart.

DR. FINKLER, of Bonn: A word only respecting the antipyretic action of alcohol. The stronger antipyretics, antipyrine, antifebrin, etc., have spoiled us for the weaker ones. At the same time, is this sudden and considerable fall of the temperature always desirable? Quinine and alcohol do not act so quickly, it is true, but their effect is more lasting, and they also have certainly an antiparasitic action.

DR. VON JAKSCH: I agree with Dr. Erb that alcohol is contraindicated in acute affections of the brain and kidneys. As regards the question of chronic alcoholism consecutive to the therapeutic employ of alcohol, I cannot accept the opinion of Dr. Juergensen, without reserve.

— Many of the sorts of food consumed in the far East are certainly not appetizing in contemplation; though occidental gourmards do not altogether avoid morbid specimens in their dietary; as, for instance, is the fatty livers of the Strasburg geese. The Medical Press say of the legendary edible birds-nests of the Chinese that they are the product of the salivary secretion of these birds, and the most *recherché* of them contain a certain proportion of blood. This variety is extremely rare, and the blood is said to be due to a malady resembling phthisis, to which swallows are liable, and which occasions sanguineous expectoration. They are only obtainable in the spring. Local tradition affirms that the birds which produce these delicacies never live more than two winters, and ultimately die of exhaustion. Chinese doctors attribute numerous hygienic and health-preserving qualities to these nests as an article of diet. They are said to be sovereign against pulmonary affections, asthma, colic, and "feeling bad" generally. The costliness and rarity of the article are probably accountable for the esteem in which it is held.

EXCESSES AND ABUSES IN ATHLETIC SPORTS.

At the last meeting of the Board of Overseers of Harvard College, a Committee of five of their number, previously appointed to consider the subject of the excesses and abuses in athletic sports at the University, rendered their report. There was a majority and a minority report, the former signed by four members of the Committee, the latter by Dr. H. P. Walcott alone.

The following closing sentences of the majority report give the substance of the conclusions reached and the form of the recommendations made:

"Your Committee are satisfied that a certain portion of the students devote altogether too much time to athletic sports; that this excessive interest is caused by the intercollegiate contests; that these contests do not tend to promote a generally diffused interest in athletic exercise, but rather to discourage it; that they interfere very seriously with the college work; and that they have an unhealthy moral influence on the students in the ways that have been pointed out. No good result of these contests has been suggested to counterbalance these arguments against them, in which no account is taken of the physical dangers attending them. The committee feel that ample opportunities for all reasonable competition can be found among the members of the university, whose undergraduates alone number more than one thousand, and that the measures which they recommend will be likely to promote a more general and more reasonable interest in athletic exercise than is possible under existing conditions. The evil moral, and physical results which attend all intercollegiate contests will, in a less degree only, attend any, and it is invidious to select where each has so many friends.

"The majority of the committee have reached the conclusion that to remedy the existing evils it is necessary to prohibit all intercollegiate contests and to place the supervision of athletic exercises in the university itself under the control of a committee in which the faculty shall have a stronger influence.

"They therefore recommend the adoption of the following votes:

"*Voted*, That the faculty be requested to prohibit any undergraduate from taking part in any athletic contest with the students of any other college or with any organization not belonging to the university during the college year.

"*Voted*, That the existing committee on athletics should be increased from five to seven by adding thereto one member of the faculty and one undergraduate, and that this committee should be given the entire supervision and control of all athletic exercises within the precincts of the university, subject to the authority of the faculty."

¶ We give the full text of the very much briefer minority report, signed by Dr. Walcott, who was for

several years a member of the Athletic Committee of the College, and as such had ample opportunity for direct personal observation of the men participating in the preliminary training and of the contests themselves:

"From such information as he has been able to obtain, he does not believe that excesses and abuses in athletic sports exist to the degree popularly represented; nor does he believe that the abuses which actually do exist are limited to the intercollegiate contests, but may and do appear at the athletic exhibitions which take place within the precincts of the college. He is confident that the best remedy for these excesses lies in intelligent control, not in prohibition; and that this control can be more efficiently exercised by a body which contains a representation of the students than by immediate prohibition on the part of the governing bodies of the university. He believes that the athletic committee of the college, as at present organized, has exercised a salutary and restraining influence; but agrees with the majority of the committee that an enlargement of the former body in the manner designated by your committee would be advantageous. In justice to the athletic committee he desires to record his own experience while a member of it—that the undergraduate members have, almost without exception, showed a spirit of wisdom and self-restraint worthy of the highest praise.

"Under these circumstances he is very reluctant to recommend any measure which would be held by that committee to be opposed to the best interests for athletic exercises. For this reason, as well as from his own convictions, he does not join in recommending the abolition of all the intercollegiate contests, but does advise that they be regulated in the following manner:

"(1) That the formal intercollegiate contests be limited to Yale, and that university teams be alone permitted to take part in them.

"(2) That these contests take place only at New Haven, Cambridge, or such other New England city or town as the athletic committee may from time to time designate."

According to information furnished the Committee by Dr. Sargent, Chairman of the College Committee on Athletics, which was established some years ago by the faculty, during the last College year there were ninety-four athletic contests of different kinds, thirty-four of which took place out of Cambridge, as is shown by the following table:

	No. played	Out of town	No. engaged	Out of town	On Saturday	Out of town not on Saturday	Total number of contests, including those in precincts of college, more or less
1886-87							
Athletic	8	1	80	35	6	0	120
Baseball	21	7	15	15	8	3	45
Boating	4	2	40	11	1	1	55
Football	14	5	30	30	7	2	50
Lacrosse	11	3	15	15	4	3	25
Tennis	3	1	50	10
Cricket	4	4	15	15	4	0	25
Shooting	6	1	10	10	3	1	26
Freshman baseball	14	5	15	15	8	1	25
Freshman boating	2	1	10	10	..	1	25
Freshman football	4	4	15	15	2	2	45
Freshman lacrosse	3	..	15	15

Of these, fifty were intercollegiate contests, and twenty-six were with amateur athletic organizations not connected with any college. The other eighteen were among the students

themselves and of these, seven were of the class designated as "athletic" in the table, which includes "such sports as are given in the gymnasium and on the track and grounds in preparation for the Mott Haven games," five were freshmen baseball games, two were tennis matches, one was a lacrosse match, and the remaining three were boat races. Of these contests, the football games all occur between the beginning of the year and the first of December, while the others, except the contests in the gymnasium, mainly occur in the spring and early summer.

It is obvious that the subject with which the Overseers' Committee has attempted to grapple is a very complex one. There has been a constantly increasing tendency during the last twenty-five or thirty years towards the extinction at our colleges and universities of the weak-eyed, shallow-chested, anæmic-faced, shambling scholar, of his ways and works, and towards the physical reformation of such progeny as he fortuitously succeeded in leaving behind him. In the course of this desirable process it is not unlikely that an opposite extreme has at last been reached, for it is useless to deny that as a people we do things in extremes. The athletic contests are probably too numerous, the anticipation of such opportunities occupies a disproportionate place in the minds of many school-boys, and the realization of such anticipation in practice and participation consumes a disproportionate amount of the thought and time of not a few undergraduates. Occasionally a man is injured physically, though very rarely seriously. But granted this, it still seems to us that the middle course, as recommended by Dr. Wallcut, is the safe one—that an intelligent control is possible which should make prohibition unnecessary. A consideration of present evils is incomplete which does not take into careful account the evils replaced and the evils ready to claim succession. There is and will be a growing class of young men in our country with whom study is not and need not be a primary object of the college course. Such a class may or may not be a desirable result of our social development, but it exists and must be recognized. For such, athletic sports, even with their attendant excitements, offer almost a salvation. That athletic sports should flourish there must be the stimulus of rivalry, of competition.

On the other hand, the college athlete is by no manner of means necessarily a neglecter of books,—as was shown some years ago in an annual report of the President of the University—and when he does study, we believe he studies to unusual advantage. His presence in the gymnasium attracts others to it, and he himself is quite convinced—probably not without reason—that his presence in the college attracts others to it. The athletic undergraduate may perhaps be regarded as too prejudiced to view fairly the questions involved, even if his judgment were sufficiently mature to enable him to do so fully, and with him the average first impression probably will be that the Overseers' Committee seeks to deal a death-blow at the prosperity of the College and the cause of liberal education; that the elective system is robbed of the perfect flower of its largest usefulness when confined to the class and lecture rooms—a view,

the sober second thought, of which he is capable, would probably modify.

We are convinced that there is enough sound common sense, good judgment, and intelligent observation among recent graduates who have been interested in athletic pursuits to make an expression of their views as to the existence of excesses and abuses and the best remedies for such of very positive value, and we hope the present discussion, aroused by the report on which we comment, will not be closed without a well-considered expression of opinion on the part of both the recent and the under-graduates.

ANTIPYRINE AND ANTIFEBRIN AS NERVOUS SEDATIVES; COMPARISON WITH SOLANIN.

At the recent meeting of the French Association for the Advancement of Sciences (March 20), Sarda de Montpellier, read a paper with the above title. His study was based on a hundred and thirty observations. He had found antipyrine to be especially useful in acute rheumatism, in migraine, in neuralgias of recent date, and in all pains of a paroxysmal character. In all such cases, it had proved its superiority to antifebrin. On the other hand, antifebrin had been equally beneficial in the pains of locomotor ataxia and in chronic rheumatism; in fact, in the latter affection and in all cases of pain of long-standing, antifebrin had shown itself to be the better analgesic.

In combating phenomena of motor excitation, epileptoid trepidation, exaggerated reflexes, tremblings, antipyrine has been of but little benefit; it has given negative results in paralysis agitans, tic douloureux, and has had but little effect on the reflex spasms (hiccough, eructations, etc.) of the hysterical. In these cases, acetanilide has given better results, except in paralysis agitans, in which it fails altogether. These two medicaments are very rarely followed by unpleasant symptoms, such as vomiting, exanthematous rashes, profuse sweatings.

Acetanilide is better borne by the stomach than antipyrine. Solanin is a very useful nervine medication whenever one wishes to obtain a depressant action on the bulbous or spinal cord. It proves a paralyzer to the motor nerves, and an analgesic to the sensory. Inefficacious in acute articular rheumatism, solanin succeeds very well in muscular rheumatism; it acts as well as acetanilide in allaying the pains attending ulcer of the stomach, as these observations show.

It is much superior to both antipyrine and antifebrin in the treatment of old and rebellious sciaticas, and in obstinate neuritis. Its influence is as marked as that of the other medicaments in calming the pains of locomotor ataxia. But it is chiefly as a moderator of motor excitation, that solanin is destined to do good service. In two cases of chronic myelitis with "douleurs fulgurantes" and epileptoid trepidation, the therapeutic effects were remarkably rapid and constant; the pains and the trepidation ceased. In a case of disseminated sclerosis with trembling of the

left superior member, the results were more remarkable still. After four days of treatment, the trembling had almost ceased and on the sixth day it was gone altogether.

In paralysis agitans, in tic douloureux of the face, in post-hemiplegic hemiathetosis, the results were less pronounced but too small doses may have been given. At any rate, further trial of this remedy in these diseased conditions is recommended. The average dose is twenty-five to thirty centigrammes per day, in divided doses. This medicament always is well tolerated.

In the discussion which followed the paper of Sarda, Professor Grasset remarked that solanin is especially adapted to combat the medullary symptoms produced by lesion of the lateral columns of the spinal cord. In epileptoid trepidation notably, and in the trembling of *sclerose en plaques*, solanin works wonders. The effects are, perhaps, not very lasting, but tolerance is so complete that one can return to it from time to time and give the patient a relief that he cannot so well obtain from any other remedy.

One serious objection to solanin is its cost, which is ten francs per gramme on the Continent.

THE UTILIZATION OF DISEASE FOR THE DESTRUCTION OF RABBITS IN AUSTRALIA.

THE suggestion of the use of disease for the destruction of rabbits in Australia is evidently exciting great interest in that distant colony of Great Britain, and the question of the means that shall be adopted for its supervision is discussed in an interesting article in the *Australasian Medical Gazette*. "Rabbits are a great fact," the editor remarks, "and failing their destruction, ruin to Australia is imminent." The Minister for Lands in New South Wales, in whose department the administration of matters relating to rabbits has recently been placed, has asked the governments of the other colonies to coöperate with the mother colony in the appointment of a Commission to advise on the subject. There is some doubt as to the proposed constitution of this Commission, and the *Gazette* believes that the most practicable and effective body would be constituted as follows: A human pathologist recommended by the council of the Royal College of Physicians of London; a veterinary surgeon appointed by the governing body of the Royal Veterinary College of London; a pupil of Pasteur, and one educated under Drs. Virchow and Koch. A body such as this would be perfectly competent, and would be able to make its experiments and tests personally in the districts where the disease, if used at all, will have to be employed, and its conclusions would everywhere be received with respect.

The inquiry is a perfectly new departure, in which there is no experience to guide, and it is the duty of the governments concerned to create an experience by experiments which will enable them to decide what had best be done in the interests of the colonies. "The subject is no trivial one, and it is one in which

thorough inquiry can be shirked no longer. A decision will have to be come to, for disease will be used; in fact, is being used for rabbit destruction, and unless some exact knowledge is created, the people of Australia will have all the risk and but a small proportion of the benefit they would have were it carried on under supervision, with an accurate record of the result."

The whole matter is not merely an exceedingly curious one to us at this distance, but such wholesale experiments with disease ought to give not only interesting, but instructive data. If it is possible to destroy in the manner contemplated a colony of rabbits, other governments may interest themselves in the destruction in a similar manner of other pests; and it requires no great stretch of imagination to see disease called in to rid the earth of such pests as the mosquitoes and black flies that render uninhabitable such large portions of territory.

TREATMENT OF POLYURIA BY ANTIPYRINE.

At a late meeting of the Société de Thérapeutique, Paris, Dr. Huchard read a communication, in which he vaunted the good effects of antipyrine in polyuria of nervous origin. At a subsequent meeting, Dujardin-Beaumetz reported the result of his treatment of three cases of saccharine diabetes by half-drachm doses of antipyrine; in all, the quantity of urine under the administration of antipyrine was reduced from six litres to three litres per day. Serreol said that he also tried the same remedy in a case of diabetes with excessive polyuria in a child, but without any favorable result.

MEDICAL NOTES.

— Small-pox is extremely prevalent in Philadelphia, and it seems not unlikely that the country at large may be on the verge of a serious epidemic. The disease is reported from centres of population both in the West and the East. Its introduction and distribution are probably due to commercial intercourse with Cuba, and immigration from Italy.

— The *Northwestern Lancet*, commenting on our recent editorial remarks on a work written for the laity on the management of pregnancy, in which all women are encouraged in expecting to secure a painless labor, provided they follow a certain regimen, says: "The regimen referred to consists principally in the avoidance of 'bone-forming foods,' so-called, a most pernicious piece of advice, which, if rigorously followed, may indeed make the labor easier, but at the expense of the child, which is likely to be puny and rachitic. We have seen within a year such a case, where the mother, after reading some such work as 'Tokology,' lived entirely upon fruit and vegetables during gestation. The child's skull was as soft and thin as parchment; it was ill-developed, and the rosary of rickets was well marked. It perished of acute bronchitis after a miserable existence of a few

weeks. An older child which had not been experimented upon was healthy and vigorous. These cases are not rare, and such works as 'Tokology' should be interdicted."

BOSTON AND NEW ENGLAND.

— The Boston City Government has appropriated a sum of money to build the new out-patient building at the City Hospital, and also a sum for the publication of another volume of the Hospital Report. The Hospital now has \$35,000 for an out-patient building.

— From the "Annual Report of the Lowell Hospital Association," January 1, 1888, we learn that a training school for nurses has been established in the Hospital, and that a course of twenty-four lectures on nursing was provided during the past winter.

NEW YORK.

A DEATH FROM ANTHRAX.

— A man forty-five years of age died at the New York Hospital a few days ago of anthrax, contracted while handling hides in a wholesale leather establishment where he worked. The symptoms, which were attributed by the patient to the bite of an insect which he supposed to have come from the hides, first appeared three days before admission to the hospital, and the swelling in the neck became so great that it was necessary to perform tracheotomy on account of the danger of suffocation. It is thought that a stiffened portion of the hide which he was carrying on his shoulder scratched his neck, and thus inoculated him with the anthrax bacillus. At the autopsy abundant evidence was found of the presence of malignant œdema, and specimens of the blood and tissues were secured for the purpose of cultivating the anthrax bacillus, if possible.

— It is certainly remarkable that the deaths of two such eminent specialists in ophthalmology and otology as Drs. Agnew and Loring, who were for a number of years associated in practice, should have occurred so near together, and the loss to the profession and the community will be a serious one.

PHILADELPHIA.

— The alumni and students of the University of Pennsylvania, on the 24th ult., held an Agnew Jubilee in honor of the completion of half a century of active practice of medicine by their veteran professor of surgery. Addresses were made by Provost Pepper and Prof. S. W. Gross, and a jewel was presented to Professor Agnew, who made a fitting response. Music was supplied by the Glee Club and the band of the University. A number of invited guests were present.

— By an odd coincidence, a celebration was held on the 27th, during the same week, of the completion of sixty years' active practice of Dr. Hiram Corson, at his home at Plymouth, Pa. The event was honored by a dinner by the Montgomery County Medical Society, to which some of the older friends of Dr. Corson were invited.

Miscellany.

AGARICINE.

THE *Therapeutic Gazette* calls attention to a remedy which has been used in Philadelphia for the last two years with alleged extraordinary success by some German physicians, in the treatment of colligative sweats. In phthisis and similar exhaustive diseases, belladonna will usually arrest sweating with certainty, but the dryness of the mouth which it produces is always very disagreeable to patients, and in some cases to it is superadded the unrest or nervous excitement, which entirely forbids the further employment of the mydriatic. Sulphuric and gallic acids often fail. The remedy that we especially allude is agaricine, the powdered *Agaricus alba*, or ordinary European agaric, a peculiar toadstool or fungus which grows upon the European larch. There is prepared an impure alcoholic extract of this fungus, which is sold under the name *agaricine*, and has been very highly praised by both English and German physicians. (See *Prag. Med. Wochen.*, 1884, Vol. ix, p. 305, and *Centralb. Klin. Med.*, 1884, Vol. v, p. 89). The dose of this extract is one grain to one and one-half grains, although it is affirmed larger quantities can be given without detriment. The effects are said to be immediate, without disagreeable accompaniments or sequels.

OBITUARY.—EDWARD GREELY LORING, M.D.

It is doubtful whether the decease of any other member of the medical profession whose practice had been entirely outside of Boston could have caused such a shock to so large a circle of relatives, friends and colleagues here as did the sudden death of Dr. E. G. Loring, which occurred in New York on Monday, April 23d, in his fifty-first year. He was born in Boston in 1837, being the second son of Judge E. G. Loring, his mother having been Miss Harriet Boott. His boyhood was passed in Boston, and at Winthrop, where his father has a summer residence. It was at Winthrop that, while a mere boy, his great fondness for and practical skill in boating was developed, which he retained to his last day. He was a pupil of Mr. Gardiner at the Boston Latin School, and in 1857 entered Harvard College, in the class of 1861. His father—who had moved to Cambridge after his appointment to a professorship in the Harvard Law School, having been removed from his position as Judge of Probate by Governor Banks, after his decision on the case of the fugitive slave Anthony Burns, which came before him as United States Commissioner,—was appointed Judge of the United States Court of Claims, by Buchanan, and moved with his family to Washington.

Loring left college at the end of his sophomore year (1859) and went abroad. He began his medical studies in Florence, and passed three years between Florence and Pisa, following the lectures and Hospital services, and having also the private instruction of Dr. Grysanovski, a German physician of great ability. At the University of Pisa he especially devoted himself to anatomy, under Professor Duranti, one of the best known anatomical teachers of that time, and who will be remembered as delegate from Rome to the International Congress at Washington last summer. In 1862 Loring returned to Boston, and after two years' work at the Harvard Medical School, took his degree in 1864. The following year he passed in Boston perfecting himself in the special branch of the profession to which he had decided to devote himself. He obtained the position of ophthalmic externe at the City Hos-

pital, under Dr. H. W. Williams, and assiduously followed the service of the surgeons at the Massachusetts Eye and Ear Infirmary, especially that of his friend Dr. Hasket Derby, of which he took charge during a short visit by Dr. Derby to Europe. In 1865 he married a daughter of James Jackson Davis, and established himself in Baltimore, where his professional career opened very auspiciously. Having, however, the opportunity to enter a professional co-partnership with Dr. Agnew, in New York, he did so in 1866. Since the dissolution of this partnership he has continued his practice in New York. His wife died some years ago, and he married, in 1886, a Miss Swift. On Monday, the 23d of April, he left his house between 2 and 3 P.M., apparently perfectly well, although it appears that he had for two days spoken of a slight pain in his chest, which he attributed to indigestion. At about 6 P.M., while standing on the corner of Park Avenue and a street up which he, in all probability, had come, after a visit to his yacht, in the building and fitting out of which he was much interested, he was seen to stagger, grasp at a lamp-post, and fall over backwards. A policeman who saw him fall found him just breathing, but life had departed before he had been moved.

Dr. Loring will be best known professionally by his improvement of the ophthalmoscope, of which one of his colleagues and friends, writes: "It may justly be said, that for elegance of construction, easiness of management and compact usefulness, its equal remains to be found. It is emphatically the best ophthalmoscope in use here or abroad. I was at the Ophthalmic Congress in Milan (1880), when he exhibited it, and the room rang with applause after his demonstration was concluded."

He contributed several articles to medical literature

chiefly on subjects connected with ophthalmic physics, which have been published in the transactions of the Ophthalmological Society, The American, New York and Boston Medical Journals, the Medical Record, etc. The first volume of his "Text Book of Ophthalmoscopy," was published in 1886, by Appleton, New York, and he had not yet completed the second volume. He had served as surgeon at the Brooklyn Eye and Ear, and was one of the original staff of the Manhattan Eye and Ear Hospitals and at the time of his death was surgeon at the New York Eye and Ear Infirmary. He was a member of the New York and American Ophthalmological Societies.

A notice of Dr. Loring, even in a medical journal, would not be complete, which only referred to his professional standing, as his individual character was such as to make him universally liked and esteemed. Although modest, refined, and even sensitive by nature, he was strong in his convictions of right and wrong, and held to them, and he had a most uncompromising scorn for all sham and pretence in professional as well as private life. Most social, in the best sense of the term, he was always a favorite with both the men and women with whom he was brought in contact. As a boy he was devoted to certain out-door sports, in all of which he excelled, such as rowing, skating, shooting, sailing, etc. His love for the salt water clung to him to the end, as he was overseeing the furnishing of a yacht, the third that he had built, in which he was looking forward to passing some weeks of the coming summer, as he had several of the past ones, cruising along our coast with his brother, Dr. F. B. Loring, of Washington. In his domestic relations he was most lovable, and to his widow, aged parents, brother and sisters, the loss will be irreplaceable.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 21, 1888.

Deaths reported 2,022: under five years of age 689; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fever) 280, acute lung diseases 192, consumption 292, diphtheria and croup 93, scarlet fever 40, diarrheal diseases 35, typhoid fever 29, measles 26, whooping-cough 15, puerperal fever 12, cerebro-spinal meningitis 12, malarial fever 11, small-pox 10, erysipelas four. From diarrheal diseases New York 19, Philadelphia seven, Boston, Pittsburgh and Washington two each, Worcester, Baltimore and Nashville one each. From measles, New York 10, Baltimore eight, Washington four, Milwaukee two, Pittsburgh and Nashville one each. From whooping-cough New York seven, Boston three, Baltimore two, Lowell, Philadelphia and Charleston one each. From cerebro-spinal meningitis, New York six, Worcester, Lowell, Cambridge, Lynn, Milwaukee and Washington one each. From puerperal fever, New York five, Washington two, Worcester, Newton, Milwaukee, Pittsburgh, and Nashville one each. From malarial fever New York five, Philadelphia, Baltimore and Washington two each. From small-

pox New York seven, Philadelphia three. From erysipelas New York three, Washington one.

In the 28 greater towns of England and Wales with an estimated population of 4,398,273, for the week ending April 7th, the death-rate was 19.9. Deaths reported 3,584: infants under one year of age 814; acute diseases of the respiratory organs (London) 419, whooping-cough 141, scarlet fever 46, measles 4, diarrhoea 41, diphtheria 27, fevers 51, small-pox (Sheffield 14, Leeds, Halifax and Manchester one each) 17.

The death-rates ranged from 13.6 in Derby to 29.7 in Manchester: Birmingham 18.5; Bradford 18.4; Bristol 21.9; Hull 15.6; Leeds 21.2; Liverpool 19.3; London 19.4; Newcastle-on-Tyne 18.1; Nottingham 15.1; Portsmouth 19.1; Sheffield 23.4; Sunderland 15.0.

In Edinburgh 22.0; Glasgow 24.4; Dublin 27.8.

The meteorological record for the week ending April 21, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barometer.		Thermometer.		Relative Humidity.			Direction of Wind.		Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 21, 1888, TO APRIL 27, 1888.

BAILY, Jos C., lieutenant colonel and assistant medical purveyor. Granted leave of absence for twenty days on surgeon's certificate of disability, with permission to apply for an extension. S. O. 92, A. G. O., April 21, 1888.

BAILY, J. C., lieutenant colonel and assistant medical purveyor. Will transfer the public funds for which he is responsible and the charge of the medical purveying depot in New York City, temporarily, to Capt. Henry Johnson, medical storekeeper. S. O. 92, A. G. O., April 21, 1888.

Paragraph 13, S. O. 89, A. G. O., April 18, is revoked by Paragraph 1, S. O. 93, A. G. O., April 23, and Major George M. Sternberg, Surgeon, United States Army, is directed to proceed to the island of Cuba for the purpose named in the letter of the President addressed to the Secretary of War, on the 17th inst. Upon the completion of this duty will return to his proper station, and submit his report to the President on or before June 25, 1888.

VICKERY, R. S., major, and surgeon. Granted leave of absence for four months, with permission to apply for an extension of two months and to go beyond sea. S. O. 95, A. G. O., April 25, 1888.

The operation of Paragraph 17, S. O. 79, c. A. G. O., (so much thereof as relative to Capt. George E. Bushnell, Assistant Surgeon, United States Army), is suspended until May 1, 1888. S. O. 90, A. G. O., April 19, 1888.

WOOD, LEONARD, first lieutenant and assistant surgeon. Granted one month's leave of absence, with permission to apply for an extension of two months. S. O. 41, Department of Arizona, April 18, 1888.

ANDERSON, CHAS. L. G., first lieutenant and assistant surgeon. Granted one month's leave of absence from June 1, 1888. Resignation accepted by the President, to take effect July 1, 1888. S. O. 92, A. G. O., April 21, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING APRIL 28, 1888.

OVERLY, A. S., medical inspector. Granted six months' leave with permission to visit Europe.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—There will be a meeting of this Society at 19 Boylston Place, on Monday evening, May 7th, at eight o'clock. The Treasurer will be present to receive the Annual Assessment, which is now due. Papers: Dr. F. W. Johnson, "A Few Cases of Abdominal Section." Dr. B. F. Davenport, "The Detection of Morphine in the Urine as a Means of Diagnosis."

T. F. SHEERMAN, M.D., Secretary.

NORFOLK DISTRICT MEDICAL SOCIETY.—The annual meeting will be held at Rockland Hall, 2343 Washington Street, Roxbury, Tuesday, May 8th, at 2 P. M. Examination by the Censors will begin at 1 P. M., of the same day.

Order of Business: (1) Records. (2) Reports from Committees. (3) Report of Treasurer. (4) Election of Officers. (5) Incidental Business. (6) Communications: (a) "A Case of Acute Suppurative Peritonitis of the Left Side: Laparotomy (by Dr. Geo. W. Gay); Recovery." E. P. Gerry, M.D. (b) "The Use of Electricity in the Treatment of Uterine Fibroids, with Report of a Successful Case," J. H. Thurlow, M.D. (7) Introduction of Newly Elected Officers.

S. ALLEN POTTER, M.D., Secretary.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, May 10th, at 7.45 o'clock. Papers: Dr. C. W. Townsend, "Endemic Cerebro-Spinal Meningitis." Dr. Henry Jackson will report two cases. Drs. S. G. Webster and T. M. Rotch will open the discussion. Dr. H. H. Osgood, "Invertebrate Headache." Drs. J. J. Putnam, E. G. Cutler, and E. N. Whittier will open the discussion.

ALBERT N. BLODGETT, M.D., Secretary.

A. L. MASON, M.D., Chairman.

APPOINTMENT.

Dr. Otis K. Newell has been appointed Surgeon to Out-Patients in the Massachusetts General Hospital.

A NEW PRINCIPLE IN THE SURGERY OF THE BLADDER.¹

BY OTIS K. NEWELL, M.D.,

Assistant Demonstrator of Anatomy at the Harvard Medical School,
Surgeon to Out-Patients at the Massachusetts General Hospital.

IN the study of any subject we are very apt to find that it has been more or less thoroughly investigated and understood in previous times, and we are led to conclude when we come upon such long since learned and forgotten facts that there is at least no wholly "new thing under the sun." In the *Boston Medical and Surgical Journal* of November 10, 1887, is an extract by Dr. G. L. Goodale, from an article entitled "Observations on Hydrophobia," written in 1812 by James Thacher, M.D., of Plymouth, Mass., in which the experiments were outlined and apologized for as chimerical and visionary which Pasteur seventy years later carried into practical execution. The recent erection of a statue in this city reminds us that Columbus discovered the land of Americus Vesputius, only to have it shown a few centuries later that one if not several enterprising individuals had already preceded him in that commendable undertaking. Many similar instances are familiar to us, both in medical and other history, and I therefore imagine that we should not be discouraged in our efforts to improve or originate in connection with any particular subject, because it may have already undergone more or less consideration.

The fact upon which whatever there may be of value in the present paper is based, I have found to be known of in one instance, where Professor Grünfeld, in his work on endoscopy, refers to the introduction into the bladder of an instrument fifteen centimetres in length. There may be other instances of a knowledge of this fact, but the practical applications which extended consideration of its possibilities has suggested to me have not, so far as I am aware, been made until now.

I refer to the fact, already laid stress upon in an article of mine published in the *Boston Medical and Surgical Journal* of November 11, 1886, that the applied anatomy of the male urethra is such that in no case is it necessary to have an instrument of more than six inches in length in order to introduce it into the male bladder and leave from one to two and a-half inches protruding through the vesical orifice. This being the fact, we see that in the average case a still shorter instrument can be introduced, and we may decide upon four and six inches as the necessary extremes of this measurement. Practically, however, an instrument of five or six inches length is the best for ready manipulation. Of course there are exceptions to this rule, but in a quite extended experience in the matter I have yet failed to find such a case. It is of interest to know that a hip may be so ankylosed, or a prostate so enormously and peculiarly enlarged, that no instrument at all, or only a specially constructed one, can be introduced into the bladder. But the knowledge of such cases is more of value to us because we may once or twice in a lifetime encounter them, than matter of everyday importance.

If we consider the anatomy of the bladder in the male and female subject we will remember that practically it differs but little in that portion posterior to

Figure 1.

the pubic arch. This, as ordinarily shown, may be seen in Figure 1, a median sagittal frozen section, taken from Dittel's volume in the *Deutsche Chirurgie* on "Stricturen der Harnröhre." The great difference, then, is found in the anterior or pendulous portion of the urethra in the male. This part of the canal, however, is so readily folded upon itself that its measurements may be easily very much reduced. This, I think, may be very clearly seen in Figures 11 and 111 taken from a frozen section of the male, which I made after introducing a split sound marked off into centimetres. The perfectly straight course of the canal when held upon an instrument is plainly seen, and the short 10 c.m. distance between the orifices equally apparent. To demonstrate the short measurement it is only necessary to introduce any unyielding instrument, straight or curved, into the bladder, so as to have one or two inches of its length protruding into the vesical cavity. If the urethra be now pushed together upon the instrument so as to appose its walls as much as possible in the longitudinal direction, without the use of undue force, and the instrument grasped at the point where the external meatus lies: when this is done and then withdrawn, the length beyond the point grasped by the fingers will indicate that of the instrument necessary to readily enter the bladder. Whoever will take the trouble to do this will not be long in becoming convinced of the truth of the stated facts, and, indeed, will begin to realize that by this procedure the parts may be made to correspond closely to those in the female, for in the majority of cases the length of instrument required to merely reach from orifice to orifice will seldom be more than from three and one-half to four inches. In Fig. 111, where the parts were not pushed forcibly together, the distance as shown is about eleven centimetres, or say four and one-quarter inches.

¹ Read before the Boston Society of Medical Sciences, January 17, 1888.

Granting, for the present, that such is the case, it will be well, perhaps, to describe in what manner the instrument should be introduced, for it is quite apparent that, being less in length than the undisturbed normal adult male urethra, it cannot possess the distinguishing advantage which its substitutes, particularly the steel sound, are sometimes said to have, of "going in just by their own weight." On the contrary, it is necessary to guide the present instrument by intelligent manipulation, but of no greater degree than the surgeon capable of introducing unyielding instruments

than long enough when of the standard length, six inches, to reach this point without being covered. When this is done, the instrument should be depressed so as to correspond in direction with the urethral axis of the prostate as much as possible, and then passed, preferably with a rotary motion, into the bladder cavity. After it has been thus introduced the prostate is fixed upon some portion of its length, and the instrument can, therefore, as a rule, be easily elevated to an angle of about 45° with the table. In thus introducing it it is best to make the whole movement in one continuous rotation and anterior progression of the instrument in the medium sagittal plane of the body, for then, when its point reaches the opening in the triangular ligament it will, since it is being always gently pressed forward and upward, pass through and not beyond that structure, to form a pocket, which it does do when first passed directly down as far as possible, a method often suggested.

Figure II.

Figure III.

into the bladder is always sure to possess. If the instrument be straight, and I believe, as will be stated more fully further on, that all instruments for introduction into the bladder should ordinarily be straight, it should be passed down until it reaches the opening in the triangular ligament. If the instrument is not up to the urethra in calibre, the parts will, by their own weight, naturally fall together upon it, and it will be more

Figure IV.

If we pass before us in a somewhat historical review the ordinary bladder instruments, as we can do by referring to Figure IV, we shall find that there is but little departure from the traditional length, and that wherever this has occurred it has rarely been but to add something to it. On the left of the figure we see various forms of lithotrites, in all of which the part for insertion is of about the same length. On the right are a number of the more modern instruments compared with those of the short measurement. Over IX and X a catheter and sound of the usual length. At XIV and XV Dr. Bigelow's divulsor and one of his evacuating tubes. Over VIII a catheter, the enormous length (eighteen inches) and curve of which were supposed to better enable it to overcome the difficulty of passing an enlarged prostate.

Figure V.

In Figure V we see a steel sound, such as one made by Ultzman, introduced into the bladder. The prep-

uration is from a full-sized adult negro, and the vesico-urethral measurements are much above the average. That is, the urethra, pendulous portion, is longer than usual, and the bladder easily distended to one litre capacity. The measurements are not altered through preparation, and the specimen is preserved for inspection. Now, it will be observed that the sound, in addition to that portion of it engaged in the urethra, measuring, as shown in the figure, 15 c.m., from meatus to vesical orifice, has still left a considerable portion protruding from either end, the outer measuring 9 c.m., the inner 7 c.m. What of these parts of the instrument are necessary? At the outer end sufficient length for convenient manipulation; at the inner, enough of the instrument to enable it to perform its specific function. For the sound, length sufficient to protrude through the prostate without stretching the

Figure VI.

bladder, as shown in Figure VI, where a six-inch sound is introduced; for the evacuating tube enough to enable its vesical end to depress the floor of the bladder so as to make it the lowest point in the cavity. An idea of what this length should be may be obtained from

Figure VII.

Figure VII; for the lithotrite the length that best fits it for manipulation of stone and strength of construction. It would seem that the shaft of lithotrites might advantageously be shortened about two inches. For a catheter, the length enabling it to best drain the bladder without making any unnecessary convolutions through which the urine is to be drawn, and which make it harder to clean. A soft rubber catheter does not need to be much longer than an inflexible instrument as far as the mere act of catheterization is concerned. When any drainage apparatus is used it is better to add it to the soft catheter than to have the latter unnecessarily long. Figure VI indicates about the proper length for metallic catheters. Eight inches seems to me to be the proper length for soft rubber catheters. They are now made thirteen to fourteen inches long. This unnecessary length is well shown in Figure VIII, taken from the fourth and fifth numbers of "Wiener Klinik," 1887, by Dr. J. Englisch, in which ninety-four pages are devoted to the consideration of catheterization. Figure IX shows a

modification of Dr. Bigelow's divulsor introduced into the bladder. This instrument measuring seven inches along the part for insertion, is sufficiently long for ready introduction, and when used is held firmly in position by the ulnar side of the hand resting over the pubes, and thus prevented from being forced into or through the bladder wall by the sudden giving way of a very resistive stricture. This, when the divulsor is used, is a very important point. The unnecessary length of a divulsor is shown by comparison in the figure. Endoscopes should, of course, offer the shortest possible visual distance, and that for an instrument to be applicable to the average case would be six inches.

Figure VIII.

If we look at the sound in Figure V, we notice that its curved end is wholly within the bladder, and that the urethral canal is practically engaged upon a straight instrument. The curved end, therefore, serves to admit of the more easy and less painful introduction, but is otherwise unnecessary. I previ-

Figure IX.

ously stated that I believed the straight instrument to be the best for most purposes, and I refer to its surgical employment, whether as an evacuator, endoscope, porte-rémède, or applicator. The usefulness of a steel sound is not interfered with by having its less painful introduction favored by a curved end, especially when it is to be used by the patient. But by removing the unnecessary three or four inches of length from urethral sounds as they are now made, we have an instrument which we know, when introduced, to be occupying a definite position in the urethral canal throughout its length, and not to be protruding indefinitely into the bladder cavity, with which it should have nothing to do. Ordinary catheterization, and especially when done by the patient, is best performed with a flexible instrument. The straight instrument is best because it is the shortest. It can best be kept aseptic, since, when properly constructed, for whatever purpose; if a tubular instrument, it can be looked through from end to end, and thoroughly cleansed by scrubbing and solutions. The chief objection to

straight instruments is that they are more difficult of introduction. But I think that none of us fail to acquire the necessary skill, and it would, perhaps, be well for mankind in general if there were fewer bladder instruments supposed to be somewhat self-introducing. As regards the difference in pain caused by the introduction of straight and curved instruments, I think that whoever is accustomed to passing straight ones has not found it great enough to interfere with the advantages of their use.

I shall not detain you with further evidence in attempting to sustain the facts as stated. In my paper of November, 1886, I mentioned fifteen cases of careful measurement, in all of which six inches had been more than the maximum necessary length of instrument. Since that time I have made many more measurements, both on the dead and living anatomy, and have become so thoroughly convinced of the truth of the matter that to add further statistics would seem to me like doing so for the mere sake of numbers. I will, therefore, in conclusion, consider what changes are suggested by the above facts in the construction of evacuators.

EVACUATORS.

In considering the construction of evacuators I have, for comparison, confined myself to that of Dr. Bigelow, with which, during two services as his House-Officer, I have had most opportunity to become familiar, and which is undoubtedly the best of the various forms hitherto made. In his article in the *American Journal of the Medical Sciences* for June, 1878, in which he established the great principle of the toleration of the bladder to instrumentation, Dr. Bigelow said, in the introductory remarks: "It is not impossible that convictions in some degree traditional may prevail in regard to certain points connected with the practice of the more recent art of lithotomy." May I possibly again suggest that another, though less important, tradition has been strangely adhered to in the construction of this and all other bladder instruments?

Figure X.

For the most effective action of an evacuator it is apparent that the distance which a fragment must be carried in order to be caught within the bulb should be as short as possible, and we should, therefore, take advantage of the fact under consideration in determining what this length may be. Now, if we compare length of the evacuating canal as shown in Figure X and Figure XI we will readily see the striking difference which the two represent, and realize the effect which must be produced by it in the rapidity of evacuation. We can readily see from the figures that a certain reduction in the length of the tube is possible. Now, another important fact is that the so-called "trap" is unnecessary, for the bulb, if properly constructed, is itself a trap. This is brought about by

making the receiver below of good size, as shown in Figure XI, so that when the fragments have fallen into it, and this they are sure to do, they are eliminated from the current, and when once through the internal orifice never returned to the bladder. This I have repeatedly proved by Dr. Bigelow's test and in other ways, and am convinced that no sort of management can make the bulb belie the fact. After full expansion of the bulb it is simply necessary to allow a second or two for the fragments to settle, and this they do rapidly, for they do not float, and then no matter how forcibly the bulb is compressed, they will remain quietly in the receiver, and *only those fragments will be driven back which have failed to be lifted through the whole length of the tube.* This may be prettily demonstrated by using a glass tube with the Ultzmann evacuator.

Figure XI.

How much now can we reduce the length of the evacuating canal? First by elimination of the trap $1\frac{1}{2}$ inches; second, by eliminating an unnecessary stop-cock, as done at times by Dr. Bigelow, and shortening the other $2\frac{1}{2}$ inches. By limiting the evacuating tube to an extreme length of six inches, four inches, making a total reduction of $7\frac{1}{2}$ inches, and thus making it necessary to lift each fragment $7\frac{1}{2}$ inches instead of 15. The present bulb is made of pure gum rubber so as not to be unnecessarily strong or heavy. A nicely finished gum bulb such as are made by the Germans cannot be produced in this country; at least so say the manufacturers. The fittings are made of hard rubber so as to be non-corrodable, disinfestable, and at the same time light. This evacuator, weighing 320 gm., while that of Dr. Bigelow weighs 725, an all-important point when they are filled with water in permitting the best manipulation and tactile sense. With the modified tube orifice as used by me, and the decreased length of canal, the gain in rapidity of evacuation is very much greater than in previous forms; in fact, beyond comparison in one sense, since tubes of this construction remove fragments which the corresponding numbers of the Bigelow pattern will not admit. If this be true, then we have not only increased rapidity of evacuation, but *diminished number of crushings.*

The operation thus consumes much less time, and its value and safety are increased. It is, perhaps, of no little importance to determine just what the value of this operation is to-day, particularly when we read of long series of cases from countries where lithotomy has never been done, and the efforts of Bigelow and others are either disregarded or set at naught. Supra-pubic cystostomy with its high mortality, and the other operations of magnitude for the removal of stone are finding their advocates who must have

further favorable evidence or condemn the Bigelow method, safer and simpler when properly taught and understood, to become obsolete. I myself have seen a distinguished authority, whose name is known to two continents, removing a stone from the bladder before an audience of various nationalities by a method taught as that of Bigelow. A Clover evacuating bulb with a small tube was used, and the crushings were performed at several sittings without anesthesia.

Figure XII.

Experience has taught me that it will be said of my tubes as shown in Figure XII, where the comparative length of the two evacuating canals is also well shown, that they are more apt to aspirate the bladder wall than the other forms. This may possibly be so, but experimentally I have never been able to determine just what the degree of difference is. Granting, however, that there is a difference, we must remember that it is of no practical importance, for when any tube is aspirating the bladder wall its orifice is either too close to that structure or else the viscus is not sufficiently distended for effective evacuation. With the Bigelow pipe attachment there is no excuse for allowing more than a few seconds to pass before correcting the latter condition. Dr. Bigelow has written that "an evacuator that works best with pieces of coal in a glass vessel of water will succeed best with the fragments in the bladder." "So also will the surgeon if he is otherwise well qualified." Experimentally there has been no trouble in evacuating coal fragments from not only a glass vessel, but from the most delicate bladder, such as one made of a chicken or turkey crop, and admirably suited to this purpose, without obstruction to the tube or injury to the bladder. This style of orifice is of great advantage in the smaller sizes of tubes, such as are used for litholapaxy in children. It is natural to expect that a certain amount of familiarity with this instrument, or with any other, is necessary before one can use it readily. Who expects to take up any complicated instrument, or piece of apparatus, and feel at home with it at once? But who will deny that there are many that work beautifully and successfully, however much or little he may favor their use?

In aspirating fragments it seems to me that it is useless to imagine that we can, by moving the tube orifice from place to place, sooner remove a fragment or fragments which may have lodged behind or within some prominence or depression about which we can know nothing, excepting, as is nowadays possible,

Figure XIII.

we take the pains to examine the bladder beforehand with the cystoscope. Under ordinary circumstances, however, it is best to place the tube so that its vesical end is depressing the bladder floor so as to make the portion with which it is in contact the lowest point. If we look at Figure XIII, taken from Dr. Bigelow's book, we will see how the tube should be held. At first the orifice is somewhat choked by an excess of fragments, but they are soon carried away, as each compression of the bulb sends them flying about in the bladder cavity, out of which they are rapidly drawn by the strong suction of the expanding bulb. In a few moments the familiar click will be heard that indicates, if nothing is falling into the receiver, that all fragments small enough have been carried through the tube. It is now, of course, of advantage to turn the orifice of the tube to one side or the other, so that with compression of the bulb any fragment or

Figure XIV.

fragments that may have lodged behind the tube will be washed away. In Figure XIV, also taken from Dr. Bigelow's book, we see casts of ten different bladders, in all of which there is no evidence of any prostate formation that would tend to interfere with the typical working of an evacuator. When peculiar malformations of the prostate or bladder, such as are occasionally met with do not admit of proceeding in the regular way, it would seem to me that the patient is exposed to less risk by some form of lithotomy. It also seems to me to be very important to have all of these operations preceded by several days of antiseptic irrigation of the bladder.

The advisable modifications in the other bladder instruments have already been suggested, by comparison chiefly, in this and a previous paper. I have no doubt that those of us who are interested in the matter will from time to time find various applications which further consideration of its possibilities may suggest.

These instruments are all made by Messrs. Codman and Shurtleff, whom I have to thank for their unfailing kindness, especially in the loan of instruments and apparatus for comparative tests.

SOUTHERN CALIFORNIA AS A HEALTH-RESORT.¹

BY SAMUEL L. DUTTON, M.D., ROXBURY, MASS.

GENTLEMEN: I have been invited to contribute, as each should be willing to do, to the general interests of the Society, and have selected "Southern California as a Health-Resort" as a subject for consideration.

"In the main, the results of personal observation will be presented, with the hope that such an interchange of views will result as shall prove mutually helpful. Such brief statistics will be introduced as may seem necessary for an understanding of the observations and opinions expressed! but further than this the writer would refer any desirous of such information to the many able publications upon the subject now extant. Many other points also desirable to introduce must of necessity be omitted, as the limits of this article will not allow of their introduction.

Presuming, then, that the tourist in going to Southern California takes the southern route, which, for the winter, is the most desirable, he will, after leaving Kansas City, travel almost directly west through the entire length of Kansas, and well into Colorado. From here he deflects to the south, soon reaching its highest altitudes, crosses the Rocky Mountains, and descends into what is known as the "Great Basin," which extends from the base of the "Rockies" to the Sierra Nevada range, a distance of about one thousand miles.

Between the Sierra Nevada and the Pacific Ocean is what is termed the Coast Range, running parallel with the Rocky Mountains, and also somewhat parallel to the sea-coast. Between these two ranges is the great Northern California Valley, drained on the north by the Sacramento River, and on south by the San Joaquin. At the foot of the San Joaquin Valley is a spur of mountains, known as the Tehachapi, running east and west, and connecting as by a band the Coast Range with the Sierra Nevada, and dividing

thereby the State north and south. At this point is Tehachapi Pass, through which communication is had between the northern and southern portions of the State. On emerging from Tehachapi Pass the tourist enters what is distinctively known as Southern California, a country possessed of a climate entirely different from that found upon the other or northern side of this ridge, the mountains acting as a barrier to the sweep of the winds from the great valley above. Turning now to the coast, we find that it runs from northwest to southeast, commencing at Cape Mendocino, and ending at Point Conception on the south, where it deflects, running almost due east and west. Along this coast runs the great Japan Current, the Gulf Stream of the Pacific Ocean, which furnishes an additional reason for an exceedingly equable climate. Bearing in mind the fact that the Great Basin in the lower part, termed the Colorado and also Mojave Desert, is separated from this section by the Sierra Nevada Range of mountains, and is, in summer, of torrid heat, it will readily be seen that the long valley of Southern California must be tempered in great measure by the air-currents passing to and fro from west to east, and east to west, thereby mutually balancing and counterbalancing one another, and thence constantly and gently fanning this territory.

Taking Los Angeles now as the illustrative point, this being the particular place to which the majority of invalids seem to gravitate, we find by comparison with Boston, and, in fact, with all sections east of the Rocky Mountains, that it has a special reason for claiming exemption from those extremes so taxing to the sick, or the man who from any cause is of weakened vitality. From the United States Signal Service Report it is shown that the average temperature at Los Angeles during January for six years has been 52° Fahr., and that for August for the same years it has been 63.7°. During these same years, Boston showed a mean temperature of 32° for January, and 69.9° for August. In other words, the warmest months in Los Angeles are slightly cooler than the same months with us, while her coldest are very much warmer. Placing it in still another form, it appears that while the greatest range in Los Angeles was 29°, in Boston it was 69°. In elevation, Los Angeles is about three hundred feet above the sea, from which it is removed twelve or fourteen miles. Eight miles farther inland, and nearer the foot-hills, is Pasadena, with an elevation of about one thousand feet.

Higher elevations still are rapidly reached as the foot-hills are approached, and but a comparatively short distance brings one to a veritable New England winter, the peaks of the Sierra Nevadas being white with snow, while seemingly hardly removed from the valley where flowers in untold quantities and variety are in full bloom and countless orange-trees are golden with fruit.

With such a climate and such surroundings certainly much can be hoped for the invalid. Still, all do not recover who go there, and in many cases for reasons that should have been avoided, and one meets many invalids who are loud in their denunciations, and who express deep regret that they ever came to the country.

On my way home, I stopped for several days at Salt Lake City, and at the hotel met no less than four persons, all strangers to one another, and equally pro-

¹ Read before the Norfolk District Medical Society.

nounced in their belief that the journey had been a mistaken one for them.

There are various reasons why a journey of this kind may be disappointing to patients and friends alike: First, many on leaving home are physically too exhausted and should never have attempted it, although I am of the opinion that, with due precautions, pretty sick men can safely undertake the trip. Again, locations are selected that do not meet the needs of the case, when a change of perhaps a few miles might have produced a different result. Too often the patient is improperly dressed, and I think I may safely say that, as a rule, he is careless and often reckless in his habits.

Carelessness has much to do with the disappointment so often experienced by the invalid, and not infrequently costs him his life. On reaching this land of sunshine and flowers, he seems possessed of the idea that Paradise is regained, and is quite apt to throw off restraint, as if in no further danger from colds, coughs, or sicknesses, and forgetful of the fact, (if, indeed, he ever knew it), that *additional* precautions should be taken, as he has yet to undergo acclimatization, until which time he remains a "tender-foot."

On our journey outward, after approaching the warm belt, I remember the train stopped one morning, owing to some obstruction upon the track, and, as is usually the case under such circumstances, many of the passengers alighted and walked about, among them two gentlemen just out of their berths, in slippers and without overcoats. Each of these had been to me the evening before, one suffering with a diarrhoea, and the other quite alarmed about a bronchial difficulty, for which he was on his way South. While stopping for a day at Las Vegas Hot Springs, some of the younger of the party were intent upon taking a bath [I think a mud-bath], although it was only for the novelty of it. At San Diego, the temptation was to indulge in bathing in the Pacific, and this January, the patient having but just left New England.

Suddenly transported to a country where oranges are as common as apples are here, this fruit was indulged in to surfeiting, with the result of producing intestinal troubles and bilious derangements. Bronchial affections already existing were aggravated, and new ills engendered, troubles that the exercise of caution might well have avoided.

Another of our party, also an invalid, determined to settle down quietly at Pasadena. This he accordingly did, commencing his life of peace and rest by purchasing a broncho, and getting in order his fishing and hunting outfit, all of which he proceeded to make vigorous use of; he had come for his health, and was determined to get his money's worth. As a consequence, he soon began to lose ground, and within a short time was worse off than when he started on his trip.

These are a few of the hazards, coming under my own observation, to which the invalid subjects himself, and one of the most important aids a physician can render is to warn him on leaving home to exercise prudence and discretion, or disappointment will certainly follow.

What classes of patients, then, shall be sent to Southern California? Where shall they be sent, and what may be reasonably expected to be the result? In answer to the first I would reply: Those who are so enfeebled as to suffer from the severities of a

Northern winter; the overworked and those needing rest; the prematurely old; the rheumatic; the sufferer from incipient phthisis; the victim of bronchial troubles; the dyspeptic; and, in fact, all generally enfeebled people. Many among these are greatly benefited by a stay of a few months, and, excepting those suffering from a respiratory disease, may generally safely return on the approach of summer, *but not earlier.*

My own observations in meeting many disappointed ones suffering from pulmonary troubles, additionally impressed upon my mind the truthfulness of what the specialist affirms; namely, that "these should make it no holiday excursion, remaining but a short time, and returning to the North at their pleasure, but, selecting some suitable place for their residence, *make this their permanent home, keeping up the constant fight for life.*"

In general, there is but little difference between the different places from Los Angeles to San Diego. They are all much alike, except as to altitude, and almost any of them safe for the invalid. If, however, the patient is one already greatly enfeebled, let him select some particular locality in which to make his home and there remain permanently, unless convinced that for some special reason it does not meet the wants of his case. Many wander aimlessly about from place to place, subjected to the hardships incident to travel and hotel life, thereby exhausting vitality more rapidly than it can be accumulated, and in the end meet with disappointment, not improving as they supposed they would, and entirely unmindful of the fact that their own indiscretion has been the cause.

Los Angeles is the Mecca of the California pilgrims, and benefits many who remain. Those who select this as their stopping place should be counselled to make their home back on the hills, which is the new section, the original or old Spanish part being at the foot. There is a lower portion of the city still, which is built upon what was at one time the bed of the Los Angeles River, since turned farther to the south. Although stoutly denied by the Los Anglean, my own belief is that malaria exists in this bottom.

Parts also of East Los Angeles are desirable places for residence, as well as Boyle Heights, across the river. Sufferers, however, from respiratory disease should not, I think, remain here permanently, but go farther to the foot-hills, the altitude of Los Angeles, as already noticed, being but three hundred feet above the sea.

Neither do I believe this to be the best place for the person suffering from nervous exhaustion, for a whirl of excitement, impossible to appreciate unless witnessed, exists here, as well as at San Diego, and is anything but restful to this class of people. Los Angeles claims, and I presume justly, more than three hundred days of fair weather during the year. This, however, is not peculiar to this city alone, but pertains as well to other places, and is certainly a factor in the treatment of disease not to be overlooked.

Pasadena, eight miles from Los Angeles, and toward the foot-hills, has an elevation of about one thousand feet. It is a charming place of about six thousand inhabitants, but is, in reality, one immense hospital. The cadaverous face is to be met everywhere, while the significant cough is heard on every street-corner, and, consequently, it is not the most cheerful of places for the victim who is himself engaged in this life and death struggle for existence.

There are other and smaller places with equally good climatic surroundings, and for these reasons, in my opinion, superior locations for the average invalid. Among them are to be mentioned Pomona, Orange, Ontario, Sierra Madre, Monrovia, and many others. San Diego, at the extreme end of the State, claims great attraction for the invalid, and shows even more days of sunshine than Los Angeles and Pasadena, although directly upon the coast, yet I learned of remarkable recoveries there.

This, however, like Los Angeles, is in a whirlwind of speculation and unrest, and therefore, but little calculated to benefit the nervously exhausted. Neither, in my opinion, should it be selected as a place of residence by any classes of invalids, for if rest and quiet are necessary in recovery from disease, it is the height of folly to send the sick man to a place where the very atmosphere is laden with the craze of excitement as with malaria. To intelligently determine the benefit the patient may expect to reap from going to this great sanitarium, and thereby answer the concluding part of our query, mortality statistics should come to our aid, but in these California is sadly deficient. On every hand one hears of marvellous recoveries, but at the same time there are many disappointed ones, who hoped for more than they realized. Individual cases are of interest, but as "a single swallow does not make a summer," so the recital of a few experiences does not establish a rule or bring us to legitimate conclusions.

In reply to a note that I addressed to our own Board of Health, the answer was that the statistics from the Pacific Coast were very unsatisfactory and meagre. The Secretary of the State Board of California commenced his last report with these words: "In presenting this report, your Secretary has to regret its many imperfections in matters appertaining to the vital statistics of the State." To appreciate the correctness of this statement, attention is asked to the report of this official for December last, in which San Francisco makes a return of its entire death-loss for that month of 38% as *unclassified*; Los Angeles 51%, Pasadena 50%, Oakland 33%, while San Diego makes no report at all, leaving us entirely in doubt as to her mortality or causes of death.

Herewith are introduced a few statistics showing the relative frequency of consumption and pneumonia in these places, as compared with Boston, and it is safe to assume that in this unclassified percentage are included others properly belonging to the respiratory diseases. In the last biennial State report the mortality in Southern California is expressed in letters, instead of figures "A" indicating absent, "R" rare, "VR" very rare, etc. Why this should be done, instead of adopting the customary course of making numerical statements, is a matter for individual conjecture. The following comparisons are for the month of December last:

BOSTON. Population, 400,000. Deaths, 872; Consumption, 123; Bronchitis, 53; Pneumonia, 89; total, 265 from respiratory diseases. Unclassified, 0.

SAN FRANCISCO. Population, 300,000. Deaths, 582; Consumption, 100; Bronchitis, 18; Pneumonia, 63; total, 181 from respiratory diseases. Unclassified, 38 per cent.

LOS ANGELES. Population, 60,000. Deaths, 60; Consumption, 10; Bronchitis, 1; Pneumonia, 4; total, 15 from respiratory diseases. Unclassified, 54 per cent.

PASADENA. Population, 5,000. Deaths, 26; Consumption, 12; Bronchitis, 0; Pneumonia, 1; total, 13 from respiratory diseases; 50 per cent. unclassified.

OAKLAND. Population, 50,000. Deaths, 53; Consumption, 4; Pneumonia, 7; Bronchitis, 0; total, 11 from respiratory diseases. Unclassified, 43 per cent.

SAN JOSE. Population, 15,000. Deaths, 30; Consumption, 7; Pneumonia, 3; total, 10 from respiratory diseases. Unclassified, 35 per cent.

SANTA CLARA. Population, 2,500. Deaths, 4; Consumption, 1; Pneumonia, 1; total, 2 from respiratory diseases. Unclassified, 25 per cent.

SANTA CRUZ. Population, 7,000. Deaths, 8; Consumption, 0; Pneumonia, 0. Unclassified, 50 per cent.

MONTREY. Population, 3,000. Deaths, 4; Consumption, 1; Pneumonia, 0; total, 1 from respiratory diseases. Unclassified, 25 per cent.

The above figures are from the monthly report of the State Board, and the only one at hand, the biennial report, as already stated, furnishing no statistics upon which calculations for the Southern section can be based. As it is one of the winter months it is fair to presume that an average number of Northern invalids is included, and consequently it is safe to assume that it is a fair comparison between Boston and these places for the average of winter.

It is not claimed that great importance should be attached to statistics of such meagre character, and I trust they will not be misleading. I think, however, that they are significant, and worthy of consideration. The places to which attention has been called were selected for comparison only, as they are among those visited by me, and the ones generally resorted to by invalids.

This large percentage of consumption is attributed, and doubtless in the main justly, to the great numbers of invalids from the Northern and Western States who, suffering from this dread disease, have gone to this country for their health, but, instead, have died among strangers. How far the same cause is responsible for the large mortality from pneumonia is an open question. Undoubtedly it is largely thus; but when we consider that, so far as San Francisco is concerned, it is not a city ordinarily thronged with tourists at this season of the year, it would appear that, contrary to popular belief, our own severe climate is not alone responsible for the mortality from this disease; neither do we suffer by comparison so much as is often asserted.

Although almost complete exemption from phthisis among the natives is claimed by some enthusiastic observers, yet attention is asked to the following extract from the last California State Report, which is from the pen of the President of the Board.

He says: "The rapid increase of the white race has steadily placed the Spanish at a sad disadvantage." "Here, as elsewhere, the rich become richer, the poor poorer, and with the inevitable attendant evil of an impoverished condition, the near future will probably witness the extinction of these earlier occupants of this sunny southwestern shore, and phthisis will have not a little to do with the ending. But the pendulum with a uniform propellant force behind it must swing in a uniform arc. Indoor residence, light houses, whether of adobe or wood, abandonment of walking and horseback exercise, must eventually do for the rich American what similar conduct is doing for the poor Spaniard."

Thus imperfectly have been presented a few of the observations and conclusions resulting from a visit to Southern California.

Another section, though not geographically included within the same limits, claims mention. I refer to

the beautiful valley of Santa Clara. This, in my estimation, is the most charming part of California that it was my privilege to visit, and to this place, I think, many patients might be sent to greater advantage than to the southern portion. If he intends making California his permanent home, and desires to engage in agriculture, this region presents superior attractions. Land is not only better in quality, but cheaper in price. But little irrigation is required, a consideration, it seems to me, that eventually will be of great importance as affecting health. Added to these are social surroundings and educational advantages that are far in advance of the lower section. Here are the beautiful towns and cities of San Jose, Santa Clara, Santa Cruz, and Monterey. At this last-named place is the famous Del Monte Hotel, the surroundings of which are charming beyond description. As a health-resort, Monterey claims advantages over any other portion of the State. Also in this valley are located the Lick Observatory, the State Normal School, and the Leland Stanford, Jr., University, with its magnificent endowment of \$20,000,000. Altogether California is a beautiful country, and possesses a climate that is beneficial to great numbers of invalids. All, however, do not recover who go there, and many would live longer by remaining at home. The length of the journey and distance from home, separation from friends, and lack of many comforts to be found nowhere outside of one's own home, lead, in many instances, to disheartening and homesickness. The expense has been great, and perhaps assumed when it could ill be afforded, with the fond hope that recovery would result. Disappointment and depression, so disastrous to the invalid, follow, and the already depleted vitality is more rapidly exhausted still. If, however, with due consideration of such qualifying circumstances a just discrimination is made in selecting patients to send to California, much good may reasonably be expected to result from the change, *provided a proper selection of location is also made, and the invalid leads a careful, uniform and temperate life in his new home.* A factor, however, that should be carefully considered as affecting his permanent recovery is very frankly and plainly set forth in the last report of the Board of Health of California, which is in the following language, and to which, in conclusion, attention is invited: "Certain chronic diseases are attributable to this climate. Now Californians [and by Californians, San Franciscans are usually meant] live a notoriously fast life. Persons coming to San Francisco from the interior or the East are at first chilled by the cool, fog-bearing winds, but this chilliness soon gives way to a feeling of exaltation and well-being difficult for those who have not experienced it to understand. No intolerable noonday heat compels a siesta. Food is bolted and digestion retarded. Their gait resembles a run, rather than a walk. Early and late their minds unceasingly act, and when their nervous force is exhausted, too often alcohol is used to stimulate their flagging energy. At fifty they are old. Such a life is conducive to nervous derangement, as well as derangements of the heart."

According to my own observation, this indictment is also true of Southern California. I was not a witness to the use of alcohol, but in other particulars I can bear testimony to the truthfulness of the charge as being far more applicable to the southern section than to San Francisco.

AN OUTBREAK OF TYPHOID FEVER IN A CHILDREN'S HOME.¹

BY W. C. HOLYOKE, M.D.

IN the fall of 1883 an outbreak of typhoid fever occurred at the Home of the Boston Children's Friend Society. It came suddenly, and ceased almost as quickly, after having affected more than half the inmates. No case has been there at any other time during my ten years' service at the institution. Notwithstanding the time that has elapsed since the sickness occurred, I have thought the matter still of sufficient interest to report.

The Home, which is favorably situated on Rutland Street, consists of a main building and a two-story wing. The main building is nearly square, and has basement, three stories and attic. On the first, or street floor, besides waiting rooms, etc., are the kitchen and the large dining room for the children. The school room is on the second floor, and the sleeping rooms for the children on the third and part of fourth, or attic, floor.

At the time of which I speak the children, who were all girls except a few boys under seven years of age, were divided into three classes. (1) School children between six and sixteen years of age, who lived in the main building. (2) The larger nursery children between four and six years of age, who occupied the lower floor of the wing during the day, but ate in the large dining room with the school children, and slept on the third floor of the main building. (3) The smaller nursery children, under four years of age, who lived in the upper story of the wing, where they ate and slept, having very little communication with the other children.

The whole number of persons in the home was 82, as follows: 50 school children, 14 in the larger nursery, 10 in the smaller nursery, and 8 adults in attendance, which was the full capacity.

In the summer of 1883 a house was procured in Milton, where most of the children spent a few weeks in turn. They all returned to the home before September 3d except the smaller nursery children, who came back about September 20th. They were then all well except two feeble children who had recently entered; and no especial sickness was noticed until October 1, when one girl complained of illness and went to bed. On October 2d a fire was started in a furnace which had been painted during the summer. The odor was very disagreeable, and produced sick headache in some of the adults. Many of the children were taken suddenly ill, and when I was called next morning I found thirty of them in bed, all complaining of about the same symptoms, as follows: headache, nausea and vomiting, and distress or pain at the epigastrium. In a few cases there was slight elevation of temperature. On the next day, October 4th, all except seven were up and about, and some of them continued well. Some of those who remained in bed gradually became feverish, and in a day or two several others who were feeling poorly went to bed. During the next ten days new cases developed every day, so that on October 16th there were thirty-seven sick in bed. From October 19th to October 31st five more came down, and a month later, or about December 1st the last case occurred, making a total of forty-three.

At first there was much doubt in regard to the na-

¹ Read before the Boston Society for Medical Observation, June 6, 1887.

ture of the disease. The sickness, which was evidently due to the odor from the painted furnace, masked for a time the disease that was developing. But as the children became more feverish a suspicion of typhoid fever was entertained, and this was placed beyond a doubt when well-marked symptoms of that disease were presented by some of the cases about October 12th.

As I was without the aid of a skilled assistant my records are not sufficiently full to allow a complete description or analysis, so that only a brief outline will be given.

A number of the cases were quite severe, others mild, and some so slight that if observed separately they could not have been called typhoid fever.

I will report briefly two cases as fair specimens of the more severe ones.

CASE I. L. P., aged eight years, went to bed October 6th. At first there was slight cough, and later the record mentions diarrhoea, tympanites, brown, dry tongue, sordes on the teeth, and a few rose spots. By degrees she became quite stupid and somewhat deaf. The temperature gradually rose at the beginning, and on October 15th was $103\frac{1}{2}^{\circ}$. It then varied between 103° and $104\frac{1}{4}^{\circ}$ until October 26th, when it began to decline, and became normal about November 1st. She sat up November 12th.

CASE II. S. K., aged thirteen years. Went to bed October 13th. Complained at first of stiff neck. Later there was epistaxis, diarrhoea, tenderness in right iliac fossa, and gurgling. On October 16th her temperature was 104° , and it remained about the same for two weeks, when it gradually fell, and she sat up November 10th.

There was one death. A feeble girl of six years was taken sick October 7th and died October 23d with peritonitis. No autopsy.

As to the individual symptoms, diarrhoea was sufficiently marked to be recorded in only nine cases, although I believe it occurred slightly in some others. Epistaxis was present in thirteen cases. Rose spots were noted only seven times. Possibly they sometimes escaped observation, but certainly they were absent in the majority of the cases. Many had slight cough throughout the sickness. Three had mild sore throat at the beginning; and in five other cases the most prominent symptom at first was stiff neck, or contraction of the muscles on one side of the neck, with pain and tenderness. Many of the children were dull and stupid, and in a few cases there was mild delirium. In other cases the dullness was less marked, and some of the children wished to sit up, but if allowed to do so they soon returned to bed.

As an indication of the degree of severity, I will mention the highest temperature recorded in each case: In 9 cases it was 101° or upwards, the highest being $101\frac{3}{4}^{\circ}$; in 8 cases, between 103° and 104° ; in 9 cases, between 102° and 103° ; in 7 cases, between 101° and 102° ; in 5 cases, between 100° and 101° ; in 5 cases, less than 100° .

Excluding the 5 cases in which the temperature did not reach 100° , the average duration from the time of taking to the bed until the temperature fell permanently below 100° was 16 days. The average time that the children were confined to the bed was 22 days. In 6 cases it was from 35 to 37 days, and in 3 it was less than 10 days. All recovered except the one before mentioned.

The number sick in each class was as follows: Of 50 school children, 35 were sick; of 14 larger nursery children, 6 were sick; of 10 smaller nursery children, 1 was sick; of 8 adults, 1 was sick.

In searching for the cause of this outbreak, many lines of investigation were followed up, with negative results. The drainage was in excellent condition; the milk and other supplies were pure; and there was nothing to be suspected about the premises at Milton. Moreover, four children who were not in Milton at all contracted the disease.

At the beginning of the sickness I suspected the water-supply on the third floor, where the school and larger nursery children were in the habit of drinking, because only those children were then affected, and the water, when first examined, was found to contain many dark specks. Its use for drinking was immediately prohibited. I then supposed that it came from a tank, but later found that the pipe led directly from the street. However, as we shall presently see, it is possible that its use had some relation to the sickness.

The most probable cause remains to be stated: On September 11th, two girls, aged seven and nine years, were brought to the Home from Chelsea. They were not well at the time of entrance, but it was thought that they were suffering merely from lack of proper care and nourishment. They continued weak and languid, sometimes up and about the house with the other children, at other times confined to bed. I was away from the city at the time, and did not see them until called to the Home, October 3d. They were then quite feeble, and appeared dull and heavy. The temperature of the oldest was 102° , which was the highest recorded in her case. It soon declined, but rose again on the 16th to $101\frac{1}{4}^{\circ}$, and again became normal in a few days. In the youngest, the temperature remained below 100° . They left the institution on November 6th. It was afterwards learned that another child of the same family, who remained at home, was sick.

Assuming that these children had the disease when they entered, it would be interesting to learn, if possible, how they could communicate it to the others. When they were able to be up they mingled with the school children, and ate with them and the larger nursery children. They also slept on the third floor with these same children. On that floor, opening from the hall in the centre, was a small water-closet, and in the hall close beside the door of the water-closet was a sink used by the children for washing, and, as before mentioned, the water was also used for drinking. These conveniences were used mostly by the school children, the larger nursery children being there only at night. This, of course, is only suggestive of a possible method of conveying the disease.

Besides the cases occurring in these two classes of children, there were two others yet to be considered. One was the landress, who was taken sick October 21st. We may readily suppose that her sickness was caused by washing the soiled clothing, which for some days, at first, was not disinfected.

The other was a little boy in the smaller nursery, who was taken sick about December 1st, or at least a month after the last of the other cases. He had three sisters at the Home, all of whom were sick. They began to sit up between the 8th and 13th of November, and immediately afterwards he was allowed to

spend some time with them. He was the only child in the smaller nursery that had much communication with the other children.

It may be claimed that some of the cases included in this report were not typhoid fever; but, presenting as they did, mild symptoms of a typhoid character, without anything else to explain the sickness, and occurring in connection with undoubted cases of that disease, it is fair to assume that they were of the same nature.

Such cases are occasionally observed in private practice, in which, perhaps, no more than a suspicion of typhoid is entertained. It would hardly seem possible that their relative proportion is as great as the present group would indicate. Yet it is not unlikely that there are many such cases not recognized or not seen by a physician, but whose influence in reproducing the disease may be very considerable.

NOTE. The disagreeable odor came from the *outside* of the furnace. It was a small, portable furnace, situated in the children's play-room in the basement. It had recently been painted a drab color, and when the fire was started a faint, bluish smoke, with disagreeable odor, was given off, which could easily pass into the hall, and so through the house. Some of the adults had sick headache for a short time, but afterwards remained well. The same is true of several of the children. The drainage was found to be all right, and has not been changed in any way since.

REPORT ON DISEASES OF THE NERVOUS SYSTEM.

BY PHILIP COOMBS KNAPP, A.M., M.D.
THE SENSE OF TEMPERATURE.

GOLDSCHNEIDER has recently published¹ an elaborate and valuable study of the sense of temperature, employing for his tests metallic cylinder a centimetre in diameter. He finds that the sensibility to temperature is not equally distributed over the whole body, but that it is most marked in the parts most richly supplied with nerves. Heat and cold are perceived separately, so that parts very sensitive to heat are not sensitive to cold. Moreover, there is a definite intensity of sensation to temperature, which cannot be increased by increasing the irritation; each spot in the skin has an "absolute sensibility." By repeated observations he has determined the various points on the body which respond to different grades of temperature, and has represented them in a series of carefully studied diagrams. In testing the temperature sense clinically the cylinder, heated to a definite point, is placed on one of the most sensitive areas, the external canthus, the first interosseous space, etc.; if there is no response there must be a decided disturbance. Sensibility to cold is greater than that to heat. A difference in perception at any point of two or three grades from that given in his diagrams is not pathological, but if two different grades are felt as the same there is some pathological disturbance. The chief source of error is in the mental condition of the patient, who should, therefore, be made first to answer to some simple tests, such as that for vision. The sensibility to temperature is easily fatigued, and this may also lead to error. The author gives many interesting pathological observations, and urges that the test for the sensibility to temperature should no longer be re-

garded as a refinement of physical examination, for it is as important, and its results are as valuable, as the tests for the other forms of sensibility.

ACUTE INFECTIOUS NEURITIS.

Rosenheim reports a case² of "acute infectious multiple neuritis" of seventeen days' duration, which came to autopsy. The symptoms were of the well-known type, and there was an acute, hemorrhagic, inflammatory process found in the affected nerves—hyperæmia, small hemorrhages and increase of nuclei. He upholds Pierson's view that the implication of the cranial nerves is more significant of this acute neuritis than of the chronic degenerative form. Careful tests for all forms of bacteria, including tubercle bacilli, were made in vain. Rosenheim recognizes the resemblance between acute neuritis and infectious disease, and its affinity with beri-beri, but on the basis of his own investigations he cannot assume an organized virus as the morbid agent in multiple neuritis. Nevertheless, he regards it as an infectious affection, due to the action of a chemical poison on the nerve. These agents he believes to be the poisonous products of tissue metamorphosis caused by bacteria, which have set up some disease elsewhere in the body. This theory explains the not infrequent development of multiple neuritis after tuberculosis or acute infectious diseases, and Rosenheim is disposed to question whether multiple neuritis ever develops spontaneously when there is no previous tuberculosis or acute infectious disease. The toxic forms, from alcohol, lead, etc., are, of course, excepted. Eisenlohr is rather disposed,³ however, to question Rosenheim's conclusions. From clinical observation he believes that spontaneous forms do occur, without any previous tuberculosis or acute infectious disease, and he has noted that the affection is commoner at certain seasons and in certain years. The question is still an open one, but, although the cases are rare, there is an increasing body of clinical support to Eisenlohr's position, so that it seems justifiable to speak of an "acute infectious" multiple neuritis.

CHRONIC ANTERIOR POLIOMYELITIS.

With an increased knowledge of multiple neuritis the existence of chronic anterior poliomyelitis, the "general sub-acute anterior spinal paralysis" of Duchenne, has been doubted. Many of the cases where the diagnosis has been made were undoubtedly cases of neuritis, and the pathological evidence rested on two autopsies, both of them made a number of years ago, and neither of them being complete. Oppenheim⁴ has now published a case with autopsy, where there is no doubt as to the condition. The patient was a woman of fifty-two, who in August, 1883, began to have weakness in the right arm, which gradually involved the other limbs until she could not walk. At no time were there pains, paræsthesia, vesical or rectal disturbances, or cerebral symptoms. The trouble was limited to the motor sphere, the muscles atrophied, and there were various forms of reaction of degeneration, but there was no typical localization of the atrophy as described by Remak. The knee-jerk was

¹A. Goldscheider. Eine neue Methode der Temperatursinnprüfung. Archiv f. Psychiatrie und Nervenkrankheiten. XVIII, 658, 1887.

²Th. Rosenheim. Zur Kenntniss der acuten infectiösen multiplen Neuritis. Archiv f. Psychiatrie u. Nervenkrankheiten. XVIII, 782, 1887.

³E. C. Eisenlohr. Ueber acute Polyneuritis und verwandte Krankheitsformen mit Rücksicht auf ihr zeitliches und örtliches Auftreten. Berliner klin. Wochenschrift. 17 Oct., 1887.

⁴H. Oppenheim. Ueber die Poliomyelitis anterior chronica. Archiv f. Psychiatrie und Nervenkrankheiten. XIX, 261, 1888.

retained at first, and there were fibrillary tremors of the muscles; later on, as the quadriceps atrophied, the knee-jerk disappeared. There was slight oedema, but no bed sores. The muscles of mastication and respiration were finally involved, and the patient died of failure of the respiratory apparatus. At the autopsy there was found an almost total disappearance of the motor ganglion cells in the anterior cornua, especially at the lumbar enlargement. Instead of them were found numerous spider cells with fine processes, a dense fibrous network, and a few free nuclei, with no material change in the vessels. The posterior cornua Clarke's column, and the rest of the cord were normal. There was a slight atrophy of the peripheral nerves, including their muscular branches, and some degeneration of the anterior roots, but this degeneration was in striking disproportion to the atrophy of the ganglion cells. There was pronounced degeneration of the affected muscles, but not as much as was expected from the complete reaction of degeneration. The case, therefore, both clinically and anatomically, answers all the requirements of chronic anterior poliomyelitis, which must still hold a place in nosology. The writer lays especial stress, in the way of diagnosis, upon the entire absence of sensory symptoms.

CEREBRAL HÆMORRHAGE.

Löwenfeld⁵ has recently published a work upon cerebral hæmorrhage which is of great value. He begins with a careful review of previous theories, and an elaborate study of the normal structure of the arteries. In discussing the morbid changes he holds that in dissecting aneurisms there is no breach in the intima or the muscular coat, but the blood probably passes through these coats by osmosis, and is extravasated beneath the adventitia. In a large number of apoplectic brains he has found a little-recognized change, granular degeneration of the muscularis, which he believes to be a senile change, although it is also seen in alcoholic subjects. He recognizes six forms of vascular dilatation, only three of which are of importance: circumscribed swellings with or without change in the vascular wall, and diffuse enlargements; the first being the common miliary aneurism. Miliary aneurisms have no connection with atheroma, but are due to a local increase in the blood-pressure, or a local change in the vessel wall causing diminished power of resistance, the latter being the commoner. Miliary aneurisms without changes in the walls are due to unrecognized changes or vaso-motor paralysis. He doubts the existence of periarteritis or atrophy of the muscularis, which are reported by Charcot and Bouchard, for the changes in the adventitia were comparatively insignificant; the inner coats showed most commonly fatty degeneration. He also rejects Turner's hypothesis of an inflammatory softening of the vessel wall. Although miliary aneurisms are often seen, Löwenfeld does not consider them as the source of the hæmorrhage, which usually comes from unexpanded vessels. In the walls of hæmorrhagic foci burst aneurisms may be seen, but they are usually also present in other parts of the brain. In renal disease without hæmorrhage the adventitia and intima are most diseased; in nephritis with hæmorrhage the muscularis is most affected. A careful study of the influence of increased blood-pressure, cardiac disease and toxic influences is

also given. In conclusion, he considers that the alterations in the vessels are due chiefly to factors emanating from the blood, which are either mechanical, dilating and rending the vessels, or due to alterations in the blood itself. The mechanical factors are:

1. More forcible action of the pumping apparatus, cardiac hypertrophy, marasmus with participation of the vessel walls without corresponding involution of the heart.

2. Obstruction of the arterial system — sclerosis, renal atrophy, obesity, constipation, sedentary habits, obstruction of the vascular system — myo-degeneration of the heart, uncompensated valvular failure, and emphysema.

3. Increase of the contents of the vascular system — plethora.

The alterations in the blood itself are:

1. Chemical: marasmus, nephritis, obesity, gout? alcohol, lead.

2. Parasitic: syphilis, rheumatism?

HEREDITARY CHOREA OF ADULTS (HUNTINGTON'S CHOREA).

In 1872, Huntington first described a form of chorea which is hereditary, and comes on only in adults. It appears in families, attacking one generation after another as the members reach adult life, but if it does not appear in one generation, the succeeding generation is sure to be free from it. It affects both sexes equally, and never appears before the age of thirty. It begins like ordinary chorea, increases to the most marked degree, and finally leads to mental disturbance, suicidal tendencies, and death. Recovery has never been observed. Huber⁶ has recently reported a case of this rare and almost forgotten form of chorea, and has made a careful study of the heredity, which has brought out a few new features. Huber's patient was a man of thirty-eight, who had been attacked by the affection at the age of thirty. The first symptoms noted were slight choreic movements of the eyes, which gradually extended to the head and limbs, until within six months it had become impossible for him to walk any distance, or to talk plainly. There were no other symptoms, except an easily induced fatigue and some disturbance of sleep, although the choreic movements had become so severe as to prevent the patient from working or from caring for himself. Inquiry into the heredity found eight other members of the family in this or previous generations who had had the disease. Huber visited the sister of his patient, who was at an asylum. She was attacked at the age of thirty-six, and the movements had increased to a most marked degree, so that her limbs and body were in constant motion, and her breathing was very irregular from the choreic movements of the diaphragm. She understood what was said to her, but could not speak. In this case, also, there were no signs of disturbance, except for the constant movements and a certain degree of mental impairment. The earliest account of any trouble was in the great-grandfather, who had four children, only one of whom was affected. One of the healthy children, however, had a son and a grandson who had the trouble, thus proving that the disease may skip a generation. The affected son, the grandfather of Huber's patients, had

⁶ A. Huber. Chorea hereditaria der Erwachsenen (Huntington'sche Chorea). Virchow's Archiv., CVIII, 267, 1887.

six children, three of whom had the disease. One of these choreic children had healthy descendants, the second died without issue, and the third was the father of Huber's two cases. None of the family, as far as known, had ordinary chorea. An autopsy on the father, who died demented, revealed pachymeningitis interna and meningitis.

Zacher⁷ has reported another case, which presents nothing materially different from Huber's case, except that his patient could temporarily control the movements. He considers the affection as allied to true chorea, in which, as is well known, psychical disturbances may occur.

PARAMYOCLONUS MULTIPLEX.

Starr⁸ reports the first case in this country of the very rare affection first described by Friedreich under the name of paramyoclonus multiplex, of which only about fifteen cases have thus far been reported. His patient was a man of thirty-three, whose symptoms came on after a strain of the muscles of the back. The characteristics of the affection, as described by Starr, are as follows: Paramyoclonus multiplex is a spasmodic affection of the muscular system, occurring bilaterally in symmetrically situated muscles attached at one or both ends to the trunk, and in muscles whose function is associated with these, consisting of a series of violent clonic spasms of considerable rapidity and severity, occurring only at intervals, and associated with fascicular tremors of the affected muscles, persisting during the interval between the spasms. It occurs after some mental or physical strain, and is not accompanied by any disturbance of sensory or motor functions, excepting by an increase of the superficial and deep reflexes. It can be excited by irritation of the skin or tendons. The muscles of the forearm and hand and of the lower leg and foot are not affected. The prognosis is favorable, and the treatment is strong galvanic currents to the spine. Starr considers it a distinct affection, which can be differentiated from chorea, hysteria, epilepsy, and even tic convulsif, to which, however, it is more or less closely allied. The nature of this affection is still unknown, although it is regarded as a functional neurosis.

VISUAL ALLOCHIRIA.

Magnin⁹ reports a curious phenomenon under the above heading, which was observed in a hypnotized hysterical patient. The patient had left hemianesthesia, but, when hypnotized, a touch on the left arm was felt as if on the right arm, and it produced contracture of the extensors of the right forearm. On testing vision, a similar phenomenon was noted. The patient detected colors with the left eye, and, when the fields of vision of the two eyes were separated by a screen, the colors were still detected by the left eye, but the vision was referred to the right. Irritation of the left conjunctiva caused the natural reflex movements in the right eye.

TRAUMATIC HYSTERICAL MONOPLEGIA.

The study of the different forms of hysterical paralysis has of late attracted the attention of many of the French observers, but none of them have investi-

gated the subject with so much care, or put our knowledge of it upon so firm a foundation as Charcot. In his latest volume¹⁰ he gives a detailed account of the affection, and advances a theory as to the nature of its production. Among other cases he describes one of a young man with a neurotic heredity, who, after a fall on the shoulder, gradually developed a paralysis of the entire arm, except the fingers. The arm was absolutely flaccid, there was no rigidity or contracture, the tendon reflexes were slightly exaggerated, and there was no atrophy. At the same time, there was a profound disturbance of sensibility over the whole arm, absolute anesthesia for all forms of sensation, and loss of muscular sense. There was, moreover, no modification of the electrical reactions, and no vaso-motor disturbance. The case is like others described by Charcot and by other French observers. That it is not due to a lesion of the peripheral nerves is shown by the fact that the anesthesia is not limited to a nerve-territory, but encircles the limb like a bracelet; that the tendon reflexes are not abolished; that there is no atrophy or reaction of degeneration; and that there were no vaso-motor disturbances in the skin. That it is not spinal is shown by the persistence of the reflexes, and the absence of atrophy and reaction of degeneration. That it is not cortical is shown by the absence of the signs of secondary degeneration—rigidity and marked exaggeration of the reflexes. It is due, however, to a disturbance in the cortex, but rather to a dynamic, functional lesion; in other words, to hysteria. Many of the cases have a neurotic heredity, and most of them show various hysterical stigmata, limitation of the visual field, hemianesthesia, etc. These paralyzes Charcot regards as identical with the paralysis dependent on idea of Reynolds. He next considers the various manifestations of hypnotism, and finds that in the cataleptic or somnambulant state there is a mental inertia, but not so great as to render it impossible to provoke various psychical functions as in a dream. The group of ideas suggested seem isolated, free from the control of the crowd of ideas which ordinarily make up the conscious *ego*, and actions thus suggested are performed mechanically. In the somnambulant stage, especially, it is easy by suggestion to produce precisely similar paralyzes. In these cases hypnotism has produced what Charcot calls an obnubilation of the *ego*, and paralysis has followed from direct suggestion. In the cases of traumatic monoplegia, the emotion caused by the accident has set up a condition of nervous shock which is allied to the somnambulant stage of hysteria. The sensation in the limb produced by this shock may be said to excite the idea of motor impotence, which may acquire force enough to be realized as a paralysis. The patient develops his own idea and suggests it.

REACTION OF DEGENERATION AND ELECTRICAL MEASUREMENTS.

Recent investigations by Stintzing¹¹ have given us many valuable data in regard to the strength of current required to produce electrical reactions, and the variations in different individuals. He has also studied

with great care the various forms of degenerative reaction, with the result of furnishing us with many new facts and of putting the subject on a new basis. He measures the galvanic current by milliamperes on an Edelmann galvanometer, and the faradic current by the distance between the two coils in millimeters (Rollenabstand). He agrees with Erb in urging the importance of considering the density of the galvanic current, as well as its intensity, but his "unit-electrode," with a surface of three square centimeters, is smaller than the "normal electrode" of Erb (10 sq. cm.). He finds that variations in electrical excitability in the same individual for different nerves is, for the faradic current, 44 mm., and for the galvanic 233 ma. For the same nerve in different individuals it is less, 21 mm. and 1.2 ma. He finds that the ordinary law of irritability holds, AnZ very rarely (one per cent.) appearing before KaZ, although there is no fixed difference in the strengths of current required to obtain them. In over seventy per cent. of the cases An SZ appeared before An OZ. The averages of electrical excitability in the different nerves are given in the accompanying table.

The importance of these figures becomes apparent in Stintzing's second paper, where he discusses the different forms of reaction of degeneration. In these different forms, the quantitative changes in the electrical excitability of muscle and nerve are found to be of considerable importance; and it is also a point of considerable value to note whether the contractions be prompt and lightning-like or slow.

His classification according to the second paper is as follows, the terms used referring to the character of the contraction, whether slow or prompt, and to the quantitative changes.

I. Highest degree. Complete reaction of degeneration with total unexcitability of the nerve.

NERVES.	MUSCLES.
1. { F., no contraction. G., none.	{ F., none, [ished. G., slow, increased or dimin.
2. { F., none. G., none.	{ F., slow, diminished. G., slow, diminished.

NERVES.

3. { F., none.
G., none.

MUSCLES.

- { F., prompt, much diminished.
G., slow, diminished.

II. High degree. Reaction of degeneration with partial excitability from the nerve.

4. { F., slow, diminished.
G., none.
5. { F., slow, normal.
G., none.
6. { F., prompt, much diminished.
G., none.
- { F., none, [ished.
G., slow, diminished or normal.
F., slow, normal.
G., slow, increased.
- { F., slow, much diminished.
G., slow, diminished.

III. Middle degree. Reaction of degeneration with retained excitability, but slowness of faradic contraction from the nerve.

(a) With slow galvanic contraction from the nerve.

7. { F., slow, much diminished.
G., very much diminished.
8. { F., slow, normal.
G., slow, normal.
- { F., none, [ished.
G., slow, diminished.
F., slow, increased or diminished.
G., slow, increased.

(b) With prompt galvanic contraction from the nerve.

9. { F., slow, diminished or much diminished.
G., prompt, much or very much diminished.
10. { F., slow, much diminished.
G., prompt, normal.
- { F., slow, much or very much diminished.
G., slow, normal or diminished.
F., slow, very much diminished.
G., prompt, much diminished.

IV. Low degree. Reaction of degeneration with prompt contraction from the nerve. (Partial reaction of degeneration of Erb).

11. { F., prompt, diminished or very much diminished.
G., prompt, diminished or very much diminished.
12. { F., prompt, much diminished or normal.
G., prompt, diminished or normal.
13. { F., prompt, diminished.
G., prompt, diminished.
- { F., none, [increased.
G., slow, much diminished or normal.
F., slow, diminished.
G., slow, increased or normal.
F., prompt, diminished.
G., slow, increased.

According to Stintzing, the quantitative changes of the polar contractions are of minor importance, although, as a rule, An SZ equals or exceeds Ka SZ only in the severer forms. Several of these forms may be found at the same time in the different nerves and muscles, according to the severity of the process; and, during the progress of the affection, a low form may change to a high one, and *vice versa*. The careful study of the forms of reaction of degeneration present in the individual case cannot fail to be of value in deciding the question of prognosis, and the papers under consideration afford us the fullest and most elaborate classification that has yet appeared.

Reports of Societies.

NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED MEETING April 16, 1888.

DR. JOSEPH E. JANVIER read a paper on

THE PRIMARY REMOVAL BY ABDOMINAL SECTION OF THE TUBE AND ITS CONTAINED FETUS IN CASES IN WHICH PREGNANCY HAS BEEN DIAGNOSTICATED, BEFORE RUPTURE OF ANY PORTION OF THE TUBE HAS OCCURRED.

This operation in question, he said, was one performed with the expectation of delivering the tube and its contained foetus intact, and done before the end of

the fourth month of gestation. In a paper read by him before the American Gynecological Society in 1886, he had advocated early laparotomy, as a rule in cases of tubal pregnancy in which hæmorrhage had occurred, (instead of resorting to the use of electricity); thus removing all possible danger of further hæmorrhage. In December of that year he reported at a meeting of the New York Obstetrical Society a case in which he had diagnosed tubal pregnancy at the fifth week, and in which death had occurred at the end of the seventh week, from a second hæmorrhage resulting from a ruptured artery on the peritoneal surface of the sac; the first hæmorrhage, which was extremely small, having taken place from the same artery nine days previously, and galvanism having in the meantime been employed to destroy the fœtus.

At that time, he said, he was convinced from this case, and from the other similar ones, that the time to operate was when preliminary or partial rupture occurred, as evidenced by the first hæmorrhage; the primary collapse symptoms constituting an almost certain indication both of the pathological condition and of the need of immediate interference. In speaking of the symptoms of tubal pregnancy he had stated that he believed that it was easier to recognize this condition than a case of hydro-salpinx, and that the presence of an irregular decidual discharge in a woman who had missed a period, associated with the normal signs of pregnancy and an enlarging, fluctuating and exquisitely sensitive mass on one side of the uterus, and followed subsequently by symptoms of shock, could hardly be referred to any other condition, even as early as the fifth week. In a case of this kind he had also said that he would certainly perform laparotomy whenever the first symptoms of internal hæmorrhage occurred.

Again, in a discussion at the January meeting of the Obstetrical Section of the New York Academy of Medicine in 1887, he had stated that in any case in which from the rational and physical symptoms he became convinced that tubal pregnancy was present, even before symptoms of a rupture of the peritoneal covering of the tube occurred, he would most earnestly urge laparotomy, and perform it if he could obtain the consent of the patient.

Dr. Janvrin then went on to say that up to the present time he had been able to find but one case on record in which the operation was performed prior to a laceration, or partial laceration, of the tube, and before the fourth month of gestation. This was one reported by Dr. Joseph Price, of Philadelphia, in the *Annals of Gynecology* (Boston) for March, 1888; and in a recent letter to Dr. Janvrin, Dr. Price had said concerning it: "The history was simply that of a delayed bleeding two weeks, and constant pain and nausea. I operated for extra-uterine pregnancy or pus-tube." He next referred to cases of laparotomy performed in tubal pregnancy, after one or more decided hæmorrhages, reported by Lawson Tait, Martin of Berlin, and others in Europe, and by Drs. A. W. Johnston, of Danville, Ky., Joseph Price, of Philadelphia, S. C. Gordon, of Portland, Me., William Gardner, of Montreal, G. W. Tuttle, of New York, and Charles B. Penrose, of Philadelphia.

All such operations, performed after there had been a rupture of some part of the tube, he thought should be classed as *secondary* operations. So far as he knew,

the credit of first advocating the propriety of resorting to abdominal section and removing the ruptured tube, with the fœtus and blood-clots, was due to an American surgeon, the late Dr. Stephen Rogers, of New York, who as long ago as 1867 urged the claims of this operation in such cases.

The advisability of enlarging this field, by removing the tube with its contained fœtus before any rupture has occurred, and during the early weeks of gestation, (instead of employing electricity for the purpose of destroying the life of the fœtus), Dr. Janvrin said he had advocated on every possible occasion during the past year and a half. Until very recently he believed that he stood almost, if not quite, alone on this point; but during the last few weeks he had found that other gynecologists also had come to the same conclusion. Thus, in the *American Journal of Obstetrics* for April, 1888, Mr. Lawson said that, although he had never as yet been called upon to operate until after the sac had ruptured, if in any instance there was a reasonable supposition that there existed a tubal pregnancy which had not yet ruptured, he should recommend immediate operation. Drs. Joseph Price and Howard A. Kelly, of Philadelphia, he believed, were also in accord with this proposition. In a recent letter to Dr. Janvrin, Dr. Kelly had said: "The history of fœtuses which have been destroyed by faradization has frequently been associated with protracted suffering to the mother, and with conditions of chronic invalidism." Dr. R. P. Harris, of Philadelphia, in the *American Journal of Obstetrics* for August, 1886, had referred to several cases in which attacks of peritonitis had occurred (when the fœtus had been killed by electricity), several years subsequent to the death of the fœtus, and due to its presence in the abdominal cavity. Mr. Tait had also very recently (*American Journal of Obstetrics* for April, 1888), pointed out the danger of the placenta's going on to develop enormously after the fœtus had died from natural causes.

Up to the present time, however, the weight of opinion among American gynecologists was decidedly in favor of destroying the fœtus by electricity in some form, in cases in which a diagnosis had been made prior to the fifth month, and in which there had been no decided hæmorrhage from the sac wall. Among the advocates of this measure stood Thomas, Lusk, Garrigues, Mundé and others of New York, and M. D. Mann, of Buffalo; and each of these, as well as others throughout the country, had had excellent results with it. In the *Annals of Gynecology* for February, 1888, Dr. Mann had stated that Dr. Janvrin was able to find only three cases in literature, including his own, where rupture of a vessel caused death without rupture of the sac. Since the publication of his paper before the American Gynaecological Society, however, he had seen one other case in which this condition was fully demonstrated at the autopsy. Two other important specimens he had recently seen in cases in which abdominal section was performed. In one of these the fœtus had died from pressure of blood-clots, at about the end of the third month, and several other attacks of hæmorrhage had occurred between this date and the seventh month, when the tube, fœtus, clots, etc., were removed. In the second case, where laparotomy was performed at the seventh or eighth week, there was a history of slight hæmorrhage from the sac wall and slight peritonitis for a week or ten days prior to its removal.

In the paper referred to, Dr. Mann had expressed the opinion that if rupture has not occurred electricity should take the place of laparotomy. To this proposition Dr. Janvrin said that he would assent, provided no experienced laparotomist could be found to operate, but not otherwise. With a capable operator at command he would urge abdominal section just as soon as the diagnosis had been made, and before any hemorrhage from the sac, with its subsequent attacks of peritonitis, could take place. These frequently recurring attacks of slight hemorrhage were exceedingly dangerous to the life of the mother, and when they had occurred, and the time came when laparotomy must be performed, the patient was in bad condition for the operation; while the procedure itself was much more complicated than at an earlier period. The same thing could be said in reference to waiting to perform laparotomy until serious symptoms had supervened, after the fetus had been killed by electricity. Then, too, there would be more or less adhesions to deal with, and the work to be done would be much more difficult than the removal of a simply enlarged and still unruptured tube containing the fetus, with no products of inflammatory processes to interfere with its early extraction.

DISCUSSION.

Dr. W. T. Lusk said that he wished he could be convinced by the arguments advanced in the paper that the time had come for the doing away with galvanism in the treatment of tubal pregnancy. It would certainly be very gratifying if we could always perform laparotomy as soon as this condition was diagnosed, as the operator would thus secure an amount of relief which was not possible when electricity was employed. Destruction of the fetus by the latter was a far less brilliant method of procedure, and when it was attended with successful results the operator was not infrequently subjected to insinuations that extra-uterine pregnancy had never existed at all. At the same time, he was so thoroughly convinced that these cases could be efficiently and safely treated with galvanism after the appearance of the characteristic colicky pains that he did not as yet feel justified in abandoning so satisfactory a method. The operation was a very simple one, requiring no special skill, so that it could be practiced by any one; and, as a rule, the results were all that could be desired.

Dr. Lusk went on to say that he had had two of his cases, occurring in private practice, under observation for a long period; one of them for six years and the other for four years. At the time the first of these patients was operated on it was thought that she was dying. After consultation with Dr. Thomas it was decided to employ electricity, and the result was entirely satisfactory. There had never been the slightest bad effect, and at the present time the mass remaining was about the size of a pigeon's egg. In the second case, in which there had been the colicky pains and other usual symptoms connected with tubal pregnancy, the tumor was now about the size of an English walnut. Since the operation the patient had given birth to a living child, and there had been no trouble whatever at the time it was born.

Now, if we had such an efficient method which was perfectly safe in the great majority of instances, he could see no good reason for giving it up. Even if inflammation, suppuration, or ulceration should ensue

we could usually perform laparotomy under such circumstances with satisfactory results. He was, therefore, convinced that in the present state of our knowledge this was the best mode of proceeding. As to performing laparotomy before rupture of any portion of the tube had occurred, the difficulty of diagnosis at this time was exceedingly great, and Lawson Tait had told him personally that he did not feel able to make it; or at least this was what Dr. Lusk understood him to say.

In regard to the other five cases which he had treated with electricity he could not speak with the same confidence as of the two just mentioned. The results were satisfactory at the time, but as the women were hospital patients he had not been able to follow up their subsequent history. If he could be convinced that laparotomy was just as safe as electricity he should certainly join the ranks of those who advocated this procedure. As to the danger of the growth of the placenta after the fetus had been destroyed, this seemed to him to be very slight, and, in fact, he questioned very much whether such a danger really existed at all.

Dr. GEORGE J. HARRISON said that his experience with galvanism had been very favorable. He had certainly destroyed the fetus by this means in three cases. He had examined one of these patients two years after the operation and had found the sac much shrunken. Since then the woman had given birth to a child in a normal manner. There had also been no evil results in his other cases. Notwithstanding this, however, he thought the experience of the profession was at present too limited to enable us to arrive at any definite conclusions and the tendency of modern gynecology was undoubtedly to advance in the line indicated by Dr. Janvrin. The results obtained by some of the German operators especially had been such as to have great weight in convincing him of the practicability of laparotomy in this connection. Still, at the present time he was not quite willing to declare himself in favor of the general adoption of the procedure in this class of cases. The statement of Dr. Janvrin in regard to the presence of extreme sensitiveness in the tumor of tubal pregnancy being one of the diagnostic signs of the condition he thought, should perhaps be somewhat modified, as he had himself observed instances in which this did not exist.

Dr. ANDREW F. CURRIER said that his opinions on this subject were largely theoretical. It seemed to him one of the inconsistencies of modern gynecology that while the abdomen was constantly being opened for the removal of tumors which might be doing the patient no injury, operators should refuse to do the same for the relief of a condition which, if uninterfered with, was absolutely sure to prove fatal, and should leave the case to the uncertainties of a method like electricity, although in many, perhaps most cases, the latter had proved successful. Men, he thought were apt to be influenced by their surroundings, and if some of those who were the strongest advocates of electricity should meet with a fatal result in any of their cases, they would not perhaps be so enthusiastic in its favor. Several years ago, the late Professor White, of Buffalo, had advanced the proposition (which he thought was a very sound one), that whenever there is in the abdominal cavity an extraneous body which is liable to cause fatal results, the proper surgical course is to open the abdomen and remove it.

Again, the possibility of the subsequent growth of parts connected with the fetus ought not to be ignored, since such men as Tait and Knowsley Thornton had spoken of it as a very serious danger.

When gynecologists performed laparotomy so frequently for ordinary pyo-salpinx or hydro-salpinx, why should they hesitate to open the abdomen for so grave a condition as tubal pregnancy? Probably the reason why this matter had not attracted more attention than it had was because these cases were so seldom seen. If this were the case, it showed the importance of more fully warning those who were to become family practitioners, as well as those who were to become mothers, of the dangers of such an accident and the necessity for the early recognition of the condition. So far as he was aware, but little attention was paid to the subject in the medical schools.

Dr. Lusk said that in considering laparotomy in connection with pyo- or hydro-salpinx and with tubal pregnancy, it was important to remember that there was this difference, that while the former conditions could not be removed by electricity, it was, as a rule, entirely feasible to put an end to tubal pregnancy by this means. If this were practicable in the case of pyo-salpinx also, he did not think it would be right to resort to laparotomy until electricity had first been tried. He then spoke of the importance, in arriving at a correct diagnosis in many cases, of making a thorough examination of the patient under ether, and referred to two cases in his own experience illustrating this point.

Dr. A. PALMER DUDLEY said that the all-important point seemed to him to be the question of diagnosis, and he should very much like to know how to make the diagnosis. Even Mr. Tait, according to Dr. Lusk, had confessed his inability to do this before any rupture had taken place. If the diagnosis were once established, the matter of treatment was sufficiently easy, whether electricity or laparotomy were resorted to. Under the circumstances referred to by Dr. Janvrin, laparotomy was a comparatively simple operation, and no more dangerous than when it was done for hydro- or pyo-salpinx. Dr. Dudley then related a case which seemed to him to show very strongly the difficulty of making a correct diagnosis. The patient was a young married woman of seventeen, who was irregular in her monthly periods, and who had already had one child. The cervix uteri was soft, and she suffered from nausea and vomiting. There was a pulsating soft tumor, extremely sensitive to the touch, which Dr. Dudley thought was probably due to tubal pregnancy. He proposed laparotomy, but this was refused, and the patient passed from observation. Two months afterward she returned to the hospital clinic, still suffering from nausea and vomiting, and at this time she consented to the operation. This was performed two weeks ago, and on opening the abdominal cavity he found pyo-salpinx on the right side, while the tube was twisted around so that its fimbriated extremity was attached to the bladder, behind which the ovary was lodged. The fimbriated extremity of the other tube was attached to the rectum, while under the pyo-salpinx there was a parovarian cyst. There was a frightful hemorrhage during the operation, but the patient was now recovering. Here, then, was a condition other than tubal pregnancy, giving rise to the symptoms which Dr. Janvrin had mentioned as

characteristic of the latter. In conclusion, he said, that he would not hesitate to resort to laparotomy early if he was able to make the diagnosis of tubal pregnancy.

Dr. Dudley having stated, in reply to a question by Dr. Janvrin, that in the case which he had narrated he had not observed an irregular decidual discharge, Dr. Janvrin said that he regarded this as the most important point in the diagnosis of tubal pregnancy. If the symptoms which he had mentioned (leaving out those of shock, which were due to rupture) were noted in any case, he thought there would be no difficulty in making out the diagnosis before rupture of any portion of the tube had occurred. These, it would be remembered, were the presence of an irregular discharge in a woman who had missed a period, associated with the normal signs of pregnancy and an enlarging, fluctuating, and exquisitely sensitive mass on one side of the uterus.

Dr. Lusk had stated that after the employment of electricity there was very little danger of inflammation, ulceration, and other bad effects. This was no doubt true as a rule, but certain cases had been reported in which it had been followed by evil results. Thus, Dr. Mann had published in the article referred to in the *Annals of Gynecology*, two such cases. As to Mr. Tait's views on the diagnosis of tubal pregnancy before rupture, in the very last number of the *American Journal of Obstetrics* (April, 1888), he stated that he had never been able to make the diagnosis at this time because he had not been called in any case until after rupture had occurred. The German cases referred to by Dr. Harrison were all secondary operations, and, so far as he was aware, the only primary operation which had as yet ever been performed was that of Dr. Price, of Philadelphia, which was done in September last.

Recent Literature.

The Principles and Practice of Operative Surgery. By STEPHEN SMITH, A.M., M.D., etc. New and thoroughly revised edition. Illustrated with 1,005 woodcuts. Philadelphia: Lea Brothers & Co. 1887.

This excellent and very valuable book of 877 well-filled pages is one of the most satisfactory works on modern operative surgery yet published. Its author and publisher have apparently spared no pains to make it as far as possible an ideal, and their efforts have apparently given it a position prominent among the recent works in this department of surgery. The book is a compendium for the modern surgeon, and since the task in a field so comprehensive is by no means an easy one, the skill shown by the writer in the execution of his plan to produce his "hand-book" is much to be admired. He has recognized the impossibility of covering the entire subject in detail, and has adopted a method of giving only important facts and principles, unencumbered by a mass of theories, data, and statistics. This concise method of writing has necessitated many positive statements; but the exceedingly commendable system of references always gives the author's authority for his facts in the name of some eminent surgeon, thus furnishing also a ready clew to more extended information, should the reader wish further details.

These abundant foot-notes are ample testimony to the thoroughness and exhaustive efforts of the writer to obtain the data from which the volume is compiled. The present edition, the only revised edition since the first publication of the work in 1879, presents many changes from the original manual. The volume is much enlarged, and the text has been thoroughly revised, so as to give as far as possible the most approved methods in aseptic surgery, and the latest instruments known for operative work, the data for the former being derived from methods at present in vogue at three of the greatest surgical centres of the world; namely, Vienna, New York, and London. It is difficult to review in detail a work covering so broad a field, and containing such a vast amount of information. It would be phenomenal if, even in some minor details, such a work was found above criticism. For example, among intestinal sutures, it is rather surprising that Jobert's has found so conspicuous a place. Again, Gegenbauer is credited with the suture of Gussenbauer (page 493), but even so able a writer as Treves¹ makes similar errors, which are really of secondary importance.

Osteoclasis is also a subject where the writer has departed from the general rule, and the paragraph on this operation and its application is disappointingly brief. Strongly contrasted with this, however, is cerebral or abdominal surgery, where marked changes appear, and justly in accordance with the rapid improvements in these branches, cranio-cerebral topography being especially expanded. It can be truly said that as a hand-book for the student, a companion for the surgeon, and even as a book of reference for the physician not especially engaged in the practice of surgery, this volume will long hold a most conspicuous place, and seldom will its readers, no matter how unusual the subject, consult its pages in vain. Its compact form, excellent print, numerous illustrations, and especially its decidedly practical character, all combine to commend it.

Questions and Answers on the Essentials of Physiology. Prepared especially for Students of Medicine. By H. A. HARE, B.Sc., M.D., etc. Small 8°. pp. 170. Philadelphia: W. B. Saunders. 1888.

This appears to be the first of a series of "question books" or "quizzes," and is devoted to physiology proper. The principal facts of our present knowledge are well given, although, of course, with that exasperating brevity which the size of the book demands. In some points the information is surprisingly good and fresh; in fact, there are but few points on which serious exceptions need be taken. There is, we believe, also, an interleaved edition, in which the student may note those opinions of his special instructor; that is to say, examiner, when they differ from those of the various writers whose views are here collated. In short, those who like this sort of book will probably find it just the thing they wish to have.

—The *British Medical Journal* gives the following as the number of medical students in the following universities in the winter session just elapsed:—In Vienna, 2,287; Munich, 1,369; Berlin, 1,316; Würzburg, 556; Leipzig, 794; Prague, 566; Graz, 501; Griefswald, 471; Breslau, 382; Freiburg, 350.

THE BOSTON Medical and Surgical Journal.

THURSDAY, MAY 10, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLFS AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

TREATMENT OF CHRONIC INFECTIOUS DISEASES.

In a recent "Conference" before the Faculty of Medicine, Paris, Professor Bouchard discusses the method of treating chronic infectious diseases, in the light of modern notions of etiology. He defines disease as "the sum of functional operations and secondarily of anatomical lesions which are produced in the economy under the influence of morbid causes, and the reaction of the organism against the latter." This definition, he says, assigns to the reaction its legitimate place, while avoiding the exaggeration of the Schools, according to which the disease consists altogether in the curative effort. Sometimes this reaction is reflex, nervous, as where the combined energies of the principal systems of functions are called forth to protect the organism as a whole, and to assist the suffering part; sometimes it is local and elemental, limited to the organic particles of the tissue which is suffering the attacks of the morbid agent, and which react, on their own account, without the aid of the nervous system. Such a reaction as the latter implies, can be witnessed in any tissue, as the cornea, whose nerves are divided, and in which an eschar is made with a caustic; a process of elimination and cicatrization takes place, and wholly without nerve-influence.

Besides those cases where the reaction is sufficient, and those where it is insufficient to bring about health, that is, those that terminate in recovery, and those that terminate in death, there is a third class of cases which seem to go on neither to the one nor to the other of these results, and constitute chronic diseases.

What is a chronic disease? A disease, says Professor Bouchard, becomes chronic, not because there is not a sufficient reactional effort, but because of the permanence of the perturbing agency. Despite the incessant struggles of the economy to return to the normal state, it ever exhausts itself in futile and ineffectual efforts against a persistent cause. This permanent cause may be the pathological sequel of an acute disease, for example, a valvular lesion of the heart, stenosis of the pylorus. Another example is seen in

¹ Manual of Surgery, Vol. III, p. 266.

diabetes, although this is generally classed as a diathetic disease, that is, a disease caused by a permanent vitiation of nutrition; the cells of the economy do not consume sufficiently the sugar in a given time. The glucose, which continues to be fabricated in normal quantity, accumulates in the economy, whence result hyperglycemia and glycosuria. Here the reaction of the organism is apparent enough; it tries to get rid of the excess of saccharine matters, and does eliminate them by the urine, and without this elimination the patient would soon die of blood-poisoning; this curative effort is however insufficient, and the disease, being due to a permanent dynamic trouble, persists and becomes chronic.

Among other causes of chronic diseases, Bouchard refers to the influence of certain microbes which get possession of certain parts of the organism, and make their permanent habitat there. They are enabled to do this "because we renew incessantly the nutritive matter which they live upon, or because we destroy or eliminate certain matters which they secrete, and whose accumulation would soon compromise their activity and development." Bouchard regards the bacterial discoveries of our times as destined to revolutionize medicine as they have already revolutionized surgery. In fact, the triumphs of surgical antiseptics have made our epoch memorable in the annals of the healing art, and although the progress thereby achieved has been chiefly in the direction of prophylaxis, yet it may be affirmed that the antiseptic treatment of infections, as now incorporated in the practice of the day, has been a fruitful gain over past therapeutic methods. Favus has yielded to vigorous antiparasitic treatment, and lupus, a disease which formerly stuck fast to the individual all through his life, till he finally succumbed to general tuberculosis, has shown itself to be amenable to a suitable local medication, that is, scarification and curetting. The same may be said of chronic abscesses, and especially the so-called "cold" abscesses, and ossifluent abscesses; free incisions, with thorough drainage and copious disinfected washings, followed, if necessary, by curetting and topical applications of iodoform, often bring about a rapid cure, whereas, formerly, there was nothing for the patient to look forward to but interminable suppurations and general tubercular infection. The abdomen has been opened antiseptically for peritoneal tuberculosis, the diseased glands removed, and the patient has got well, and what has been done for the peritoneum has been done for the pleura and other serous cavities. The antiseptic treatment of empyema and chronic swellings of the joints has given especially brilliant results.

How is it with respect to cancer? This disease is already treated by surgeons as if it were an infectious disease, and we have seen the late Congress of Surgeons recommend, in order to prevent relapses, that thorough ablation should be performed before the end of the second month of the development of the disease and with the affected gland or organ all the glands in

the vicinity should be removed, even if they appear to be healthy.

Such has been the influence of microbiotic doctrines on surgical therapeutics, and we can but hope that internal pathology will ere long profit by improved knowledge of the human organism and its reactions, and of the causes of chronic maladies, whether these be animate or inanimate.

REPORT OF THE BOARD OF HEALTH OF THE CITY OF BOSTON FOR THE YEAR 1887.

If we are unwarrantably tardy in noticing this report it is not because we are indifferent to its great value. Comparatively few persons, we fear, are aware of the admirable summary which it gives of all matters relating to the health of Boston, and to its mortality during the past year; or of the importance of such a clear presentment of the facts relating to our sanitary condition as are to be found in this document.

The total death-rate for 1887 (25.18 per thousand) is larger than in any like period for several years past, which is partly accounted for by the unusual heat which prevailed during the summer months, and by the prevalence of measles or scarlatina during the latter half of the year. Moreover, no account was taken of the undoubted increase of the city's population since the census of 1880, and which alone is sufficient to account in great measure for the apparent excess of mortality over that of preceding years. "The Board of Health believes that an enumeration of the inhabitants undertaken by the police, as is done in several of our large cities, in the years which intervene between the census years, would show that our population has largely increased since the last census was taken, and that the city's death-rate is not actually so large as is here given."

A very convenient table is given on page 5, which shows at a glance the comparative mortality of twenty-five of the principal fatal diseases during the year 1887. As usual, pulmonary consumption heads the list, with 1,500 deaths, in round numbers. Since the same number of deaths from this disease occurred in 1884, when the total number of inhabitants must have been considerably less than at present, the result must be considered satisfactory. Pneumonia is the next most fatal disease, having caused 795 deaths, but it is fair to conclude that more or less of these were from other diseases which are often confounded with it, such as pulmonary oedema, from acute bronchitis, in aged persons, or patients with chronic renal and cardiac disease, and broncho-pneumonia, especially in puny children. Of 232 deaths from "pneumonia" in patients under five years of age, a considerable number were probably the result of broncho-pneumonia, a disease differing in its causes, its clinical history, its pathology, and its lesions, from genuine pneumonia.

It may surprise some of the readers of this report that "heart disease" was the third most frequent

cause of death, numbering 619 victims. Probably here, also, we must make allowance for errors in diagnosis.

The remarks on the subject of cholera infantum, emphasizing the important relation of this fatal disease to defective sanitary conditions and unwholesome diet, are most suggestive, and show the necessity of a better acquaintance with these matters among the poorer classes of the community, a want which the Massachusetts Emergency and Hygiene Association is endeavoring to supply. It is in vain to expect any great diminution of the mortality of our city until some notions, at least, of better ventilation, better cooking, and the value of cleanliness are more diffused among those who furnish the largest proportion of disease and of deaths.

There were four cases of small-pox during the year, which were removed to the hospital, and all recovered. It is somewhat remarkable that while the city maintains at a considerable expense a special building for this disease, the spread of which is preventable by vaccination, there is no hospital for the isolation of other contagious diseases, which, in the aggregate, destroyed 806 persons during the year. New wards for contagious diseases at the City Hospital, lately opened, in a measure supply this want.

We are surprised that pneumonia is not yet included among the zymotic diseases. It is now generally admitted that it is in a certain degree an infectious disease, in all probability caused by a micro-organism, even if the specific germ be not definitely settled; also that it is epidemic in certain localities and in dwellings of bad sanitary condition. Its clinical history shows it to be a zymotic. It has a definite cycle of duration. Its temperature curve is more specific than that of typhoid fever. If rheumatism be a zymotic, which we believe to be true, pneumonia should be included in the same category. One would think it could, at least, claim a better right than alcoholism.

Besides the statistics of death and of fatal diseases, there are many other subjects relating to the public health, especially in sanitary matters, which are presented in this valuable report, but which we have not space to allude to.

A GERMAN VIEW OF INTUBATION OF THE LARYNX.

At the Seventeenth Congress of the German Society of Surgery, held in Berlin April 4-7th ult., Thiersch, of Leipzig, gave his experience with O'Dwyer's method. He has performed intubation of the larynx in thirty-two cases of diphtheritic croup. In fourteen of these he was obliged to remove the tube and perform tracheotomy, on account of attacks of suffocation. Only three patients got well after intubation, and without tracheotomy. He attributed these rather discouraging results to the exceptional gravity of croup in Leipzig. Intubation, Thiersch

says, may be substituted for tracheotomy in cases of croup where there is only a limited neo-membranous formation and no swelling of the vestibule of the larynx. On the other hand, when the epiglottis is tumefied, or when there is swelling of the mucous membrane below the vocal cords, or when there is an abundant membranous formation, tracheotomy is obligatory, and intubation can do no good.

In favorable cases, amelioration appears immediately after placing the O'Dwyer canula in the wind-pipe.

Some of the inconveniences of intubation (to say nothing of its difficulties) are as follows: Deglutition is badly performed; the child swallows the wrong way. This is due to the presence of a stiff, open tube in the larynx, and there is also danger of pneumonia by aspiration (Schluck pneumonie). On this point he was disposed to lay some stress. Sometimes the child complains of pains, and indicates the seat; erosions are found in the trachea as the result of intubation, and may open the way to general infection. Sometimes the child expels the canula in a fit of coughing. Children treated by this method need constant watching, for they are in perpetual danger of oedema of the glottis, or of being choked by the membranes, and in such cases the presence of the physician is necessary to remove the tube and false membranes, and, it may be, perform tracheotomy.

Rehn, of Frankfort-on-the-Main, was of the same opinion as Thiersch on the subject of intubation. He had treated fourteen cases of croup by this method; ten of them died. The most of his patients swallowed with such difficulty after intubation that he was obliged to feed them by the cesophageal sound or by lavements. In two instances the canula was coughed up and swallowed by the patients, and afterwards passed by rectum.

Rose, of Berlin, said that he was not an advocate of intubation. He was an ardent tracheotomist, having performed the operation two thousand times, with a mortality of 71.6%. This gave him a percentage of 28.4 of cures, to offset 21% of recoveries under intubation in America.

REMOVAL OF BLOOMINGDALE ASYLUM.

SOME months ago an association interested in real estate in the upper part of the city of New York sent a memorial to the legislature requesting that streets should be cut through the grounds of the Bloomingdale Insane Asylum, (the insane department of the New York Hospital), which they claimed was not in reality a charitable institution. Since then a committee of the State Senate has been making an investigation of the charges brought against the asylum, and two reports, a majority and a minority report, have just been presented from it.

The former, signed by four members of the committee, states that after a full investigation the charge

that any denial of visitation has been made to the State Board of Charities cannot be sustained. As to the question whether or not the institution is in fact conducted as a public charity, and whether or not free patients are admitted there, the committee finds that the statement of the asylum authorities is accepted by the memorialists. The position assumed by the latter is that the system of charges adopted at the asylum takes the institution out of the category of charities and puts it on a footing with a private asylum conducted for gain. The committee is of the opinion that such cannot fairly be said to be the case. Of patients treated during the past year, eighty per cent., as appears by the report, were absolutely free patients. The report further states that it does not appear that worthy objects of charity have been excluded, so that pay patients could be received at higher cost, and that exemption from taxes bestowed upon the New York Hospital is of like character with that granted to similar institutions.

The committee visited the asylum grounds, and reached the conclusion that "under existing circumstances the public interest would not be subserved by cutting through streets to the injury, if not to the destruction, of buildings upon the asylum property, or by bringing the buildings of the asylum into close proximity to the public streets, and that in the present state of affairs there is no pressing need for the opening of the streets referred to in the memorial. . . . It would be unwise to compel a hasty abandonment of Bloomingdale Asylum even after a removal had been determined upon, which from appearance may soon be done, it will be necessary in view of the public interest, that time should be given for the completion of new buildings before the asylum is forced to abandon its present site."

A minority report, signed by two members of the committee, advises that the streets referred to should be opened within two years. This report states that if the asylum were removed its lots would be more valuable for other city purposes, recommends that it should be removed to the same relative distance from the thickly populated portion of the city as it was seventeen years ago, and furthermore claims that the city loses a large amount of taxes on account of the asylum lots being free from taxation, and that the citizens, as a rule, hesitate to have their residences near an institution of this character.

REGULATION OF HYPNOTISM.

At the recent meeting of the French Association for Advancement of Sciences at Oran, a motion was passed recommending the government to forbid the practice of hypnotism, except by physicians and as a therapeutic measure. The Belgian Academy of Medicine, at its regular session in Brussels (March 21st), had a similar resolution up for deliberation, but it will not be put to vote till the next meeting.

MEDICAL NOTES.

— The astonishing statement is made by an English contemporary that two hundred inquests were held in one year by the same English coroner on babies overlain by adults sleeping in the same bed with them. This, if true, of course indicates something worse than carelessness on the part of the parents. It is suggested that the system of infant life insurance so much in vogue in England may furnish a key to this singular mortality.

— The *Fort Wayne Medical Journal*, having indulged in the following reflections about microbes:

Some M.D.'s are downright skeptics.
Devoid of faith in antiseptics;
The very name of microbe hate,
The chief of whom is Lawson Tait.

the *Medical Standard* most pertinently remarks that this is the most severe cut Mr. Tait has had to endure; nobody previously had ventured to insinuate that he was a microbe.

— The following inducement to invalids to visit Florida is found in a Jacksonville newspaper:

"For the information of my acquaintances as well as strangers in this city, the surrounding villas, also throughout the State, I publish my system for embalming for the preservation of the dead in a manner life-like as an eminent success. My knowledge obtained from the required study with the practical operation, together with the undoubted excellence of the fluids employed and instruments used render failure an impossibility. My rooms are open all hours, day and night, hence personal calls or telegrams requiring my services either at home or any part of the State, are promptly answered. I am the oldest established undertaker in Jacksonville, with stock of metallic and wood caskets of large proportions, embracing the cheapest on up to the most expensive, and in all sizes. Bodies prepared with great care for shipment, regardless of time or distance."

BOSTON.

— A bill has been favorably reported to the State Senate from the Joint Committees on Water-Supply and Drainage to protect the purity of inland waters, and to require consultation with the State Board of Health regarding the establishment of systems of water-supply, drainage, and sewage.

— The State Legislature has, despite the advice of the State Board of Health that good oleomargarine was better than poor butter, passed a vote of discrimination and extermination against this invention, and rancid butter may now resume its sway on the tables of cheap boarding-houses, having proved itself too strong for even sweet and pure animal fat — a case of the survival of the unfittest.

— The Board of Overseers of Harvard College, after a full discussion, voted last week, 12 to 6, adopting substantially the minority report of the Committee on Athletics that, in its opinion, an undue prominence is now given to athletic contests in the College, and the exercises and abuses attending the same, and

mainly incidental to intercollegiate contests, should be checked and guarded against in the future; that intercollegiate contests should take place only in Cambridge, New Haven, or such other New England city or town as the Committee on Athletics may from time to time designate; that university teams alone should be permitted to take part in intercollegiate contests, and that students should be prohibited from taking part in contests with organizations not belonging to the university, except on Saturdays and holidays. Thus a matter of considerable practical importance seems likely to be settled on a basis which seems just and wise.

NEW YORK.

— The organization has been effected of a new charitable institution, to be known as the New Amsterdam Eye and Ear Hospital, the executive surgeon in charge of which will be Dr. T. R. Pooley.

Miscellany.

TYPHOID FEVER CAUSED BY DRINKING WATER.

ANOTHER instance has been added to the long list of epidemics of typhoid fever caused by drinking water. An epidemic broke out in February in a large boarding-school at Quimper, France, and one-sixth of all the inmates were attacked, with a mortality of one in eleven. The epidemic was confined to the Quimper boarding-school, the rest of the town being exempt.

An investigation by the health authorities showed that whereas the city in general is supplied with aqueduct water from a healthy source, the school in question obtains its drinking water from a well. Moreover the boarding-school is surmounted by a elevated plain which is a market; the washings of the excrements of human beings and animals can easily penetrate the sub-soil of the school-building premises, and contaminate the well. In fact, microscopic examinations of the water of the well are said to have revealed numbers of the characteristic typhoid bacillus.

One woman living some distance from the school, but who had been in the habit of obtaining her drinking water from the school well, took the fever and died.

DERMATOSES FOLLOWING MENTAL SHOCK.

DR. DEBOTS HAVENITH, writing in *La Clinique*, adds some further instances of dermatoses following mental shock to the case of purpura hemorrhagica recently described by Professor E. de Smet. The *Lancet* quotes the following:

"1. An unmarried lady who had been present when a man armed with a spade violently attacked another man, was much upset by the sight, and did not regain her accustomed composure for some days. Three weeks later bullæ presented themselves on different parts of the body, and before long, the entire cutaneous surface was covered with an eruption, having the characters of foliaceous pemphigus, accompanied by

incessant pruritus. Arsenic, quinine and other remedies exercised but little effect, or at least only a temporary one, for the patient succumbed, after four years, to a state of marasmus. 2. A little girl of ten was with difficulty saved from a burning house. From that time her appetite became bad, and she was haunted by constant nightmares and visions of houses on fire. A month afterwards a pemphigoid eruption made its appearance on the nose. It spread to the mouth and then disappeared. Shortly, however, it again manifested itself, covering a large part of the body. Iron and quinine appeared to be of but little service, for in nine months' time the eruption was as copious as ever. Two or three drops of Fowler's solution of arsenic three times a day soon worked a marvellous improvement, which it was evident was really due to the arsenic, for twice when the medicine was intermitted for a time the eruption returned. 3. A married woman had a quarrel with her husband, who struck her on the cheek with a key. Four days afterwards an eruption came out on the wrists, the hands, and the feet. This eruption had the characters of Hebra's multiform exudative erythema, and was accompanied by intense itching. On the lips there was a vesicular tumefied eruption and patches on the tongue. The whole disappeared in three weeks.

PERMANGANATE OF POTASH AND AMMONIA IN COBRA BITE.

A CASE of cobra bite resulting in recovery is narrated by Mr. Percy A. Rigby, Surgeon at Sonthal Pergunahs (see *Indian Medical Gazette*, Vol. xxii, No. 12, and *Practitioner*, April, 1888). A Hindu was bitten by a young cobra, two feet long, between the index and middle fingers, on the back of the hand, about 8.30 a.m. on October 21. He refused any treatment, and went home to take native medicines. At 12.30 p.m. the man was brought in a dying state to the dispensary. Though conscious, he could not stand, the respiration was gasping, and he could not raise his head. Saliva was flowing from his mouth and mucous râles obstructed respiration, the pulse was full and soft, the hand and forearm swollen, the palmar surface corresponding to the bite was livid. A hypodermic injection of permanganate of potassium (5 per cent.) was at once given in the situation of the bite; permanganate powder was rubbed into the wound; and a draught containing 20 minims of Liquor Ammonia was administered internally. At 1 p.m. the patient was gradually becoming worse. Saliva in great quantity poured from the mouth, the mucous râles were very marked, convulsive spasms occurred of body and especially of the extremities, respiration was spasmodic, the head had fallen forward on the chest, the pulse was softer. The draught of Liquor Ammonia was repeated. At 2 p.m. the symptoms had increased in severity. At 2.30 p.m. the case was seen by Mr. Rigby. The patient was apparently sinking fast; the mucus threatening suffocation, violent convulsive spasms affecting the body, respiration spasmodic, pulse 60, respiration 12 and abdominal; partial paralysis of the lower limbs, the surface of body covered with a cold clammy perspiration, the mind unimpaired. An injection of 15 minims of Liquor Ammonia in the same quantity of water was given hypodermically at the bend of the elbow, and a large mus-

tard poultice was placed over the heart. At 3 p.m. the convulsive spasms were more severe, the pulse was still more feeble, the breathing very catchy; urine and feces were passed in bed. The injection of Liquor Ammonia was repeated. Half an hour later breathing had almost ceased, although the *râles* seemed less, and the pulse had rallied in quantity, becoming firmer at 68. At 3.45 p.m. the respiration was 12, the pulse 70 and improved in tone, convulsive seizures were less frequent, the *râles* had diminished; general improvement. A draught of 20 minims of Liquor Ammonia was swallowed with much difficulty. At this point a man of his caste, coming to pray over him, placed his mouth to his ear and commenced blowing into it with great violence. The patient at once had two or three violent convulsive seizures, all the improve-

ment vanished, the pulse became almost imperceptible, the respiration about 6, the jaw dropped, and he seemed *in articulo mortis*. At 4.20 p.m. the condition being unchanged, another ammonia draught was given. The patient became drowsy, the spasms less frequent. At 4.30 p.m. the respiration became very shallow, and coma appeared to set in; but suddenly he rallied, and from this time improvement steadily continued, the pulse gradually improving, being 68 at 6 p.m. By 8 p.m. dysphagia had passed off. The treatment now consisted of stimulants in the shape of country spirit every half-hour in a like quantity of water. Next day his temperature was 101.2°, the arm much swollen. There was no ulceration from the hypodermic injections of ammonia. The bite was a genuine cobra bite, the wounds of both fangs being visible.

REPORTED MORTALITY FOR THE WEEK ENDING APRIL 28, 1888.

Deaths reported 2,210; under five years of age 816; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 300, consumption 373, acute lung diseases 301, diphtheria and croup 92, scarlet fever 54, diarrhoeal diseases 36, typhoid fever 27, measles 21, erysipelas 17, small-pox 16, whooping-cough 16, cerebro-spinal meningitis 12, malaria fever 9. From typhoid fever, Philadelphia 13, Milwaukee four, New York, Boston, and Fall River two each, District of Columbia, Pittsburgh, Nashville, and Lawrence one each. From measles, New York 9, Pittsburgh four, Baltimore and District of Columbia three each, Boston and Fall River one each. From erysipelas, New York seven, Philadelphia three, Boston and District of Columbia two each, New Orleans, Pittsburgh, and Salem one each. From small-pox, New York and Philadelphia eight each. From whooping-cough, New York eight, Baltimore three, Philadelphia two, District of Columbia, Pittsburgh, and Charleston one each. From cerebro-spinal meningitis, New York three, Phila-

delphia two, Baltimore, District of Columbia, Pittsburgh, Milwaukee, Nashville, Worcester, and Fall River one each. From malarial fever, New York four, New Orleans two, Baltimore, Nashville, and Fall River one each.

In the 28 greater towns of England and Wales with an estimated population of 5,398,275, for the week ending April 14th, the death-rate was 21.9. Deaths reported 3,952; infants under one year of age 941; whooping-cough 172, scarlet fever 46, diarrhoea 38, diphtheria 33, measles 32, fevers 21, small-pox (Sheffield 11, Blackburn three, Manchester and Bristol one each) 16.

The death-rates ranged from 34.9 in Manchester to 16.8 in Portsmouth; Birmingham 20.5; Bradford 19.5; Brighton 21.3; Hull 18.8; Leeds 21.4; Leicester, 19.2; Liverpool 22.9; London 20.6; Newcastle-on-Tyne 23.0; Nottingham 24.9; Portsmouth 19.8; Sheffield 23.5; Sunderland 17.8.

In Edinburgh 20.7; Glasgow 22.3; Dublin 27.6.

The meteorological record for the week ending April 28, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM APRIL 28, 1888, TO

By direction of the President, Surgeon Remus C. Persons, United States Navy, is assigned, temporarily, to the charge of the Army and Navy General Hospital, Hot Springs, Ark., during the absence, on leave, of Major Richard S. Vickery, Surgeon, United States Army, surgeon in charge. S. O. 96, A. G. O., April 26, 1888.

DE LOFFRE, A. A., captain and assistant surgeon. Granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. S. O. 99, A. G. O., April 30, 1888.

EMLE, GUY L., first lieutenant and assistant surgeon. Now under orders to report for duty to the commanding officer, Fort Douglas, U. T., will accompany the 8th Cavalry from Department of Texas to Department Dakota, and upon completion of this duty will proceed to Fort Douglas. S. O. 99, A. G. O., April 30, 1888.

MCCAW, WM. D., first lieutenant and assistant surgeon. Relieved from duty at Fort Leavenworth, Kan., and ordered for Missouri, May 1, 1888.

RAFFERTY, GORDEN, first lieutenant and assistant surgeon (recently appointed). Ordered for duty at Fort Clark, Tex. S. O. 98, A. G. O., April 28, 1888.

LAUDERDALE, ISO. V., captain and assistant surgeon. Ordered from Fort Clark, Tex., to Fort Davis, Tex. S. O. 98, A. G. O., April 28, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 3, 1888.

HORD, W. T., medical director, and WOOLVERTON, T., surgeon. Ordered as delegates to represent the Medical Department, Navy, at the meeting of the American Medical Association, May 8th, at Cincinnati, Ohio.

BEAUFLEY, GEO. F., surgeon. Ordered to Navy Yard, Brooklyn, N. Y., without delay.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE TWO WEEKS ENDING MAY 5, 1888.

BAILLIAGE, P. H., surgeon. To proceed to New York, N. Y., for temporary duty, May 1, 1888.

HUTTON, W. H. H., surgeon. Detailed as President of Board to report as to quarantine establishment at North Chandeleur Island, Gulf of Mexico, May 4, 1888.

WYMAN, WALTER, surgeon. Granted leave of absence for fourteen days, May 1, 1888.

STONER, G. W., surgeon. Detailed as Chairman of Board for the physical examination of candidates for appointment and promotion, Revenue Marine Service, May 5, 1888.

MERRILL, F. W., passed assistant surgeon. Detailed as Recorder of Board for the physical examination of candidates for appointment and promotion, Revenue Marine Service, May 4, 1888.

CARTER, H. R., passed assistant surgeon. Detailed as Recorder of Board to report as to quarantine establishment at North Chandeleur Island, Gulf of Mexico, May 1, 1888.

DEVAN, S. C., passed assistant surgeon. Relieved from duty at Sapelo Quarantine, to assume charge of the Service at Savannah, Ga., May 3, 1888.

WHITE, J. H., passed assistant surgeon. Relieved from duty at Savannah, Ga., to assume charge of Sapelo Quarantine Station, May 3, 1888.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.—The next regular meeting will be held at 19 Egleston Place, Monday, May 11th, at 7.45 p. m. Reader, Dr. J. J. Putnam; Subject: "Personal Observations on Multiple Scuturis." CHARLES HARRINGTON, M.D., Acting Secretary.

DR. E. G. LORING. RESOLUTIONS OF BOARD OF SURGEONS OF NEW YORK EYE AND EAR INFIRMARY.

At a special meeting of the Board of Surgeons, of the New York Eye and Ear Infirmary, held May 2, 1888, the following resolutions were adopted.

Resolved, That in the sudden death of Dr. Edward Greely Loring, the surgical Staff of the New York Eye and Ear Infirmary have lost an able and skilful colleague, who for nearly fourteen years has been a surgeon in the ophthalmic department of the Institution. His kindly and lovable personal qualities of a genial, frank and warm-hearted friend. In his professional attainments he was most eminent; enthusiastic in his devotion to his special field of work, and as one of its most distinguished exponents, he was justly esteemed an authority. We greatly deplore the cessation of his labors, while still in the full enjoyment of his powers, which were enriched by a large and carefully digested experience. As an author he was remarkable for his acute observation and logical reasoning, while the clearness of his style gave evidence of the directness of his thought. By his death scientific ophthalmology has lost an ardent and successful disciple, while the community has been deprived of the services of a skilful counsellor and practitioner.

The surgeons of the New York Eye and Ear Infirmary desire thus to give expression to their feeling of affection and respect for his memory, and sympathizing sincerely with his family in their loss, offer them their respectful condolences.

Resolved, That this minute be entered on the records of the Board of Surgeons of the Infirmary, and that a copy be sent to the family of Dr. Loring.

CHAS. STEWART BULL,
GERRARD BACON,
MORRIS J. ASCH,
Committee.

DEATH.

Died, at Manchester, Mass., April 25, 1888, George Arthur Priest, M.D., M.M.S.S., aged sixty years.

ON AXIS-TRACTION FORCEPS, THE PRINCIPLES OF THEIR CONSTRUCTION AND THEIR VALUE IN PRACTICE, WITH A DESCRIPTION OF A NEW MODEL.¹

BY EDWARD REYNOLDS, M.D.

It is a well-known mechanical law that if extension and counter-extension be applied to the ends of a rigid curved rod, the resultant force is exerted in the direction of a straight line drawn between the extremities of the rod. Now, when the ordinary curved obstetric forceps is applied to the head at the brim, and traction made upon the handles, the forceps is exactly equivalent to such a curved rod, and the force of its traction is exerted along a straight line drawn between the point at which the hands are applied and that at which its grasp upon the head is centred; a line which lies so far forward and passes so close to the pubic arch that, in the attempt to follow it, the head is drawn forcibly against the symphysis, on which a large portion of the force employed is expended. The mathematical proof of this statement has been so frequently published² that it is unnecessary to repeat it here. It is enough to say that it can be easily shown that a large portion of the force exerted is employed in bruising and injuring the soft tissues of the parturient canal, and in opposing instead of favoring descent by grinding the head against the symphysis pubis.

It is evident at a glance that if the tractions could be exerted exactly in the axis of the pelvis, or rather in the line of least resistance in the individual case, the head could be extracted by a much less powerful force, and that, moreover, the portion of force saved would be just that part which is employed in doing harm, and in impeding delivery.

In surveying the conditions of the case, one's first impressions would be that the easiest way to secure axis-traction would be by bending the handles of the forceps backward until they crossed the axis of the superior strait; and it is interesting to see that some of the earliest axis-traction instruments³ were constructed upon this plan, but these instruments were failures, and in the light of our present knowledge it is easy to understand this fact, for when we consider that the axis of the pelvis is constantly changing its degree of curvature, and that its direction must vary with each variation in the inclination of the pelvic brim, and with each variation in the shape of the individual pelvis, whether flat, normal, or universally contracted; when we consider, moreover, that the line of least resistance is not necessarily coincident with the pelvic axis, but must vary, in addition, with every variation in the shape and dimensions of the individual head, and especially with every variation in the position by which that head presents, we see at once that no such rigid instrument could ever be exactly right, unless by chance; and, moreover, that it must frequently err as badly, if not worse, than do the simple curved forceps.

These considerations are, furthermore, supported by

the fact that the first successful axis-traction instrument, that of Tarnier (1877) was one in which the line of traction could be carried backward or forward at the will of the operator, and which, in addition, by the existence of a freely movable joint between the blades and traction handles, permitted the head to move freely in any direction in the line of least resistance, under the influence of the varying intra-pelvic pressures.

The recognition of the importance of this automatic adjustment and the invention of an instrument which secured it was, in reality, Tarnier's sole contribution to the principle which is now so widely associated with his name; but the improvement was so great that the principle of axis-traction became at once prominent; and the instrument was so well adapted to its end that all the many changes in its form which have been made since that time have been made, in the case of successful instruments at least, merely in the interests of increased simplicity, and without altering the fundamental principles of its construction.

[A variety of instruments were then shown and described as follows]:

The original Tarnier model has to-day a merely historical interest. It is an efficient instrument when once in position, but is so cumbersome and complicated and of such peculiar curves that it is an extremely difficult instrument to apply. It is also difficult to clean, and is to-day obsolete, Tarnier himself having produced some thirty other models.

Lusk's model is a simplification of the older Tarnier instruments, but still clings to the Tarnier curve, which Tarnier himself has discarded. This double curve may be useful, as Lusk claims, in some few difficult cases, but renders its application far less easy, and must decrease its value for general use; indeed, Lusk himself agrees⁴ that the Simpson axis-traction forceps is, for general use, the best form yet invented.

This instrument is simply a rather large and heavy Simpson's forceps, fitted with a compression-screw, and with traction-rods, which are attached to the blades by a screw and nut; and in this lies the one fault of the instrument. The necessary removal of the rods before and after use for purposes of cleanliness, is, as in most other models, a tedious and annoying process. This difficulty is done away with in Felsenreich's modification of this model, in which the rods are attached just behind the fenestra by button-hole joints, such as are generally used in attaching the blades of surgical scissors. In his forceps the compression screw is also a separable piece of apparatus, and is attached by slipping it into a groove in the handles. These changes make the instrument more easy to clean and more convenient for use as an ordinary forceps without axis-traction.

Believing that an attachment which could be applied to any forceps at a low price, and without in any way altering the forceps, would meet a widely felt want, I have had made an instrument which I think meets these conditions, and is at once thoroughly efficient, easily applied, and still more easily kept clean.

It consists of a pair of curved traction rods, terminating at each extremity in a hook. The upper hook is intended to fit into the extremity of the fenestrum, and ends in a flat button of the size and shape which

³ Those of Habert, 1863, and of Morale, 1871.

⁴ Science and Art of Midwifery, p. 371.

has been found by experiments in actual practice to be best adapted to allow of an easy application and to ensure its retention in position. The hooks at the lower ends of the rods slip into rings attached to a traction-handle, and fit loosely enough to allow considerable rotation. The handles of the forceps are fastened by a separate clamp of simple construction, somewhat resembling a monkey-wrench.

A, forceps; B, rod; C, button by which the rod is attached; D, traction-handle; E, switch-bar to compensate for any difference in the length of the fenestra; F, clamp.

In cases in which a large head is free

above the brim of a transversely contracted pelvis, it may be necessary to attach the rods before locking the forceps, but by this method I am sure that they can be attached in any case in which the head is within the reach of the ordinary forceps. They are made by Messrs. Codman & Shurtleff.

The remaining models are less widely accepted and less to be recommended; the high forceps of Brens have been enthusiastically received at Vienna, and are in general use there, but have not been much favored elsewhere.

They are constructed upon the principle that axis-traction is of but little importance, and that the superiority of such instruments is really due to the joint between the head and handles, and they are in reality nothing more than a large pair of Simpson forceps, in which the blades are hinged to the shanks, while a couple of light rods run down from the blades and are pinned together to ensure their moving in unison. As at present made, the instrument can only be cleaned by boiling or by prolonged immersion in an antiseptic.

The next pair of forceps is that which is now used in the Rotunda at Dublin, and is a praiseworthy attempt to attach axis-traction to the ordinary (Denham) forceps, but is rather an inferior instrument. The joint is too near the hand to allow free motion to the head, and the construction of the instrument is such that it can only be cleaned by boiling or by being kept in a jar of carbolic, as is the custom at Dublin.

The next two models are interesting in comparison

with the plates of the earliest axis-traction instruments on record,⁶ which they closely resemble.

My own experience in the use of axis-traction instruments is but small, amounting to only five cases. Of these, four were delivered by other methods after the forceps had failed, but the fifth illustrates well the value of axis-traction.

In a case of marked justo-minor pelvis⁶ I applied the Brens' forceps as a precautionary measure, and after satisfying myself that the delivery of a living child was impossible, did craniotomy. I found the forceps easy to apply, but have, of course, no knowledge of their value as extractors. In three subsequent cases, in each of which the head was movable, above the brim of a flat pelvis,⁷ I made a tentative application of my own axis-traction attachment before resorting to version, and was gratified to find that the attachment of the rods to the (Vienna) forceps was easily effected, in spite of the facts that in each case the application was a very high one, and that in two of the three cases it was complicated by a want of space, due to marked transverse contraction of the brim.

In two of these cases the child was extracted by version after the failure of the forceps, (one living, one stillborn), but in the third, though version was accomplished, it was followed by craniotomy to the after-coming head.

These cases are quoted only because they are the ground for my belief that these rods can be attached to the blades after their application, in any case which is at all suited for a forceps operation.

In a fifth case the head of a large (nine pound) child was engaged (O. L. A.) at the brim of a rather small normal pelvis, and circumstances rendered immediate delivery necessary. I applied the Vienna forceps and made three strong tractions without avail. I then made a fourth very powerful traction, using all the force which I dared apply, and again without effecting any descent; I then hooked on the traction rods, and governing the handles of the forceps with one hand, took a tentative pull on the traction-handle with the other, to assure myself that everything was in place, when to my surprise I felt the head start, and increasing the force, brought it through the pelvis and on to the perineum with a single strong one-handed traction, in spite of the fact that I had previously exerted almost my whole strength upon the simple forceps, without so much as starting it.

I do not wish to be understood as having from any one case become an enthusiastic advocate of axis-traction, nor a believer in the use of high forceps rather than version, for the majority of cases; but I do feel that I shall in the future give axis-traction a thorough trial in the comparatively few cases in which I believe that the use of high forceps is the preferable operation; and I wish to present my own appliance to your notice, not as a perfect instrument and one

sued to every emergency, but as a simple and efficient form of axis-traction, easily within the reach of the general practitioner, and well suited to his use because applicable to the individual forceps with which he is already familiar.

THE USE OF HEBRA'S CONTINUAL BATH OR WATER BED IN SURGERY.

BY OTIS K. SEWELL, M.D.,

Assistant Demonstrator of Anatomy in the Harvard Medical School, Surgeon to Out-Patients at the Massachusetts General Hospital.

The subject to which I wish to call your attention to-night is one which appeared to me to be of great interest when I wrote the present paper, about three years ago. At the suggestion of Dr. H. H. A. Beach I referred the matter to the late superintendent of the Massachusetts General Hospital, Dr. Whittemore, who also took an active interest in it. Owing to his unfortunate illness, however, its further consideration at that time was postponed. For various reasons I have been unable to again attend to it until now, when, I am happy to say, Dr. Pratt, the present superintendent of the Hospital, has the construction of such a bed under consideration.

The continual bath, or water bed, of Hans Hebra had won such universal approval from those who had seen it in operation at the Vienna General Hospital that a plan and description of it was appended to the report of 1882, in order that other institutions might construct similar ones. It particularly interested me while I had opportunities of observing it in use, and after reading in regard to it, by the very great advantages which it presents for the treatment of certain surgical cases. The information given below has been obtained from the appendix to the hospital report, Kaposi's lectures, and my own observation and inquiry in regard to it. To Hebra's bed have been added improvements suggested from time to time, and the one shown in the plan has resulted. Seven such are now in use at the Vienna Hospital, and at times are simultaneously occupied. Their best use is perhaps in cases of severe burn, but they are also used to great advantage in gangrene, bed-sores, and in fact in many cases which a familiarity with the bed would show to be adapted to its use. I shall here speak particularly of extensive burns, as the great value of the bath is so apparent in their treatment. Any theoretical objections to its use are to be answered by the fact that patients have remained in the bath as long as 385 days and nights, and "taken nothing therefrom but their recovery."

There are many practical points in its favor. Severe cases of burn die here as elsewhere, but are *relieved at once of their pain*. If the case admits of recovery it progresses under the most favorable circumstances. Freed from his pain, the patient lies comfortably, and changes his position at will. Fever rapidly subsides. Sleep and appetite are acquired, and the system brought into condition to compensate for the great loss of pus. The dangers of erysipelas and sepsis are slight, and "pocketing" of pus is avoided. The severe nervous strain caused by the painful removal of more or less adherent dressings, and the necessary amount of equally painful lifting and turning are avoided. The wounds

granulate splendidly, and often so luxuriantly as to require "touching up." Pus is at once removed, instead of remaining to become putrid and fill the room with its odor. In fact, many disagreeable subjective and objective complications are obviated, and not only the patient but the attendants made comfortable. The cost of such a bed is, according to the superintendent during whose administration those in Vienna were introduced, about seventy dollars, and in addition to the outlay dependent on their use to be reckoned as slight compared with that of the dressings they replace.

The beds should be in a light, well-ventilated room, with cemented or tiled floor, and walls painted with oil colors to withstand the effects of moisture. The water-supply may be taken from the main boilers, and the waste conducted through ventilated pipes.

The bed consists of an ordinary zincked tub about .002 mm. thick, reinforced by iron bands and corner pieces, and supported by an oaken frame. At the head and foot is a windlass, to which the mattress frame is attached by chains, so as to be raised or lowered as needed. The mattress frame on which the patient has a swinging support in the water is of galvanized wrought iron, spanned with wire of similar material. To regulate the height of the patient's head and shoulders it is hinged at the upper end, so as to work like the ordinary bed rest, and may be modified to accommodate more than ordinary sized patients, as shown in figure at Z.

Filling of the tub is accomplished by a mixing vessel at the head of the bed, into which hot and cold water pipes are conducted. The water flows in through pipes at the bottom and out of waste pipes at the top. At the head of the bed is placed a strap for the patient to grasp in changing position. See figure at S.

¹ Read before the Medical Section of the Suffolk District Medical Society, March 7, 1888.

The plans are here about one thirty-fourth natural size, the smaller details on a somewhat larger scale. Originally the water was allowed to flow continuously from a boiler heated by lamp flame. It has since been found that this is superfluous, and that the water is, in addition, on account of the existence of currents, unequally warmed and renewed. On this account it is the present custom to renew the water but three times daily, and regulate its temperature in the mean time by fresh additions. As the tubs are made to hold a large quantity, 6.75 hektolitres, and are surrounded by a wooden frame covered with cross-pieces and blankets, loss of heat is slight, and the addition of fresh water but little needed. The determination of the temperature is left mostly to the patient's feelings, and these indicate, as a rule, about that of the body. At first, water at about 30° C. feels much too warm, then too cool, and must soon be raised to about 35° or 37° C., which is afterwards adhered to. Patients remain constantly in the bath, and are only raised from it for use of the bed pan or urinal. They can thus pass days, weeks, and even months uninterruptedly, while all their functions and nourishment, as much as the disease makes it possible, go on normally.

The only somewhat disagreeable complication affects the palmar and plantar surfaces, which, similarly to those of washerwomen, shrink, become white and folded, and at times cause frequent and sharp pain. This tends to subside after applying any fatty substance, and will disappear spontaneously in from two to five days. The epidermis of the rest of the body suffers no important changes. In individual cases a papulous eczema occurs on those parts subject to frequent changes from wet to dry, principally the arms and sides of the thorax. This sort of water eczema heals without treatment.

The danger of drowning, although appearing at first thought to be considerable, is slight, and in spite of the frequent use of the beds, such an occurrence has never been known. Strong and self-dependent patients awake the moment their mouths touch the water. Weak or disabled ones may be kept from sliding down by a folded cloth passed under their shoulders and arms. In private practice an ordinary or portable bath tub may be used.

Instead of using, as is the present custom, the ordinary hair mattress, it would be much more cleanly and antiseptic to use a rubber-covered mattress attached to the frame.

THE TREATMENT OF FRACTURES OF THE EXTERNAL CONDYLE OF THE HUMERUS.¹

BY GEORGE W. GAY, M.D.
Visiting Surgeon, Boston City Hospital.

FRACTURE of the external condyle of the humerus, extending more or less deeply into the elbow-joint is often difficult to treat in such a manner as to prevent deformity and impaired motion. Dislocation of the head of the radius forwards causing it to impinge upon the shaft of the humerus in flexion of the forearm is a common occurrence, and unless corrected, flexion can never be made beyond a right angle, and seldom quite to it. Another complication not infrequently met with in this injury is dislocation of the radius and ulna

backwards and outwards, thereby preventing flexion beyond a very slight degree.

To prevent the forward displacement of the radius I have made use in several instances of the ordinary internal angular splint set at an acute angle. One case, that of a child, was treated without any splint by reducing the dislocation, and placing the forearm at an acute angle and securing it in position by adhesive straps and bandages. The result was satisfactory, but I do not recommend the method for general use, as pain and other mischief might readily follow the treatment, unless great care was taken to avoid it. It is impossible for anterior displacement to take place with the arm put up at a moderately acute angle, as there is no room for the head of the radius to slip on to the anterior surface of the humerus. The angle need only be acute enough to preclude the possibility of a forward displacement of the radius.

The lateral dislocation of the radius and ulna can be controlled very satisfactorily by means of lateral angular splints, one on either side of the arm. These splints, together with the anterior, or as it is usually called, the internal angular splint, applied to an arm, afford a very complete support to the elbow-joint. The bones are held firmly in position, the joint is well supported and with the arm in a well-fitting sling the patient is usually as comfortable as can be expected.

I have never treated this class of injuries to the elbow in a straight position, and cannot see any advantages to be derived from the method. Should any ankylosis result from the injury it is far better that the forearm should be at or near a right angle, as this position enables the patient to do very much more than any other in the way of dressing, eating, etc.

The broken arm is examined every three or four days. Gentle passive motion is used after ten days, and it is varied in degree according to the indication. Care is taken not to light up a fresh inflammation by this measure, as more is lost than gained by so doing. The joint often improves in mobility for a year or more, hence a too hasty opinion should not be given in these cases.

In conclusion, I would urge upon the younger members of the Society the importance of making the first examination and dressing with the patient under ether. A more careful diagnosis can thus be made and a better position can be secured for the broken bones. Guard against an anterior dislocation of the head of the radius with the fragment of the external condyle, and also of a backward or lateral displacement of both bones of the forearm. The arm once placed at an acute angle, and properly secured in that position, it is hardly possible for either of these complications to occur.

TUBERCULOSIS OF THE PERITONEUM; EVACUATION OF ASCITES BY LAPAROTOMY; CURE.¹

BY J. W. ELLIOT, M.D.

THE patient was a delicate-looking girl of fourteen years, with red hair. Her mother brought her to me on account of an enlargement of the abdomen. This enlargement had been noticed about a year previous, and had steadily increased. The child had lost health and strength, but complained of nothing else.

¹ Read at the meeting of the Surgical Section of the Suffolk District Medical Society, March 7, 1888.

¹ Read at the meeting of the Surgical Section of the Suffolk District Medical Society, March 7, 1888.

I found the abdomen greatly distended. The enlargement was uniform. Fluctuation was evident, and hard masses were to be felt at various points. On percussion, the left flank was dull, while the right was tympanitic: there was dullness over the whole of the rest of the abdomen. The percussion note did not change on change of position.

There was a chronic vaginitis. The uterus was small and in normal position. Douglas's fossa was not bulging into the vagina. There was an anemic heart-murmur and amenorrhœa for three months. I made the probable diagnosis of ascites due to tuberculosis of the peritoneum, and for further evidence drew off some fluid, which was sent to Dr. Gannett for chemical and microscopic examination. He reported that the fluid was undoubtedly ascitic, and suggested tuberculosis of the peritoneum, although he had failed to find the tubercle-bacillus. I advised laparotomy, with evacuation of the fluid, in the hope of curing the disease. A month later the abdomen was larger, and both loins were found tympanitic, while the rest of the abdomen was dull on percussion, and change in position did not change the percussion note. This evidence caused some of the gentlemen who saw the case with me to consider it a thin-walled ovarian cyst.

On December 12, 1887, I opened the abdomen and evacuated two pails full of ascitic fluid. The peritoneum was thickened and adherent to the subperitoneal fat. The omentum, intestines, and all the organs were studded with small, hard, grayish-white lumps, which felt like shot (tubercles). The intestines were drawn up by the diseased mesentery and held in the upper abdomen, so that they did not present at the opening, nor did they fall into the pelvis after the fluid was evacuated, but air was sucked in to fill the vacuum.

The omentum was rolled up and contracted into a long mass of tissue of the size and shape of a large sausage. The ovaries and tubes were not enlarged, but were studded like the rest of the organs with tubercles. A small amount of bloody fluid was left in the pelvis, as it seemed to form about as fast as it could be sponged out.

The abdomen was closed without drainage. The operation lasted twenty minutes. Recovery was uninterrupted, the wound healing by first intention. The patient went home at the end of three weeks.

Dr. R. H. Fitz, who was present at the operation, kindly examined a bit of the peritoneum microscopically, and reported that the case was peritoneal tuberculosis. Dr. Sears found a tubercle-bacillus in one of the sections of the hardened fragments.

Four months after the operation the patient was examined at my office. She had grown fat and rosy, and said that she was perfectly well. The abdomen was flat and soft, all the hard masses having disappeared. There was no ascitic fluid present. In short, the patient seemed to be cured.²

In looking over the reported cases of laparotomy for tuberculosis of the peritoneum, I find that almost all the operations have been done either as exploratory operations or from a mistake in diagnosis. It is only within the last year or so that the operation has been deliberately undertaken for the purpose of curing the disease. Dr. Cabot's second case and this case of mine are among the first reported where, the diagnosis being made, the operation followed for the

purpose of cure, and cure resulted. This, it seems to me, is an important step forward in abdominal surgery.

So far as I am able to learn, this disease appears clinically in three forms: In the first form there is a hard, circumscribed mass of tubercular tissue at one or more points in the peritoneal cavity, *without any ascitic fluid*. There is one such case reported, where a semi-solid mass was felt in the region of the ilio-cæcal valve, which was supposed to be malignant disease, but, on opening the abdominal cavity, the cæcum and vermiform appendix were found rolled up in a hard mass, and studded with tubercles. This patient recovered entirely, although this form of disease is not usually improved by the operation.

In the second form there is an encapsuled ascites usually just above the pelvis, and the diagnosis is difficult. Like other varieties of encapsuled peritonitis, there is a tumor, evidently fluctuating, but without a definite outline, with only a vague sense of limitation.

In the third form there is free ascitic fluid, with occasional hard masses to be felt.

Out of twenty-nine cases collected by Fehling,³ twenty-one were encapsuled ascites. Of these, fifteen were cured (eight over one year previous), six died. In five cases there was free ascitic fluid; of these, two were cured and two improved. He also found that out of forty cases collected, only two were men. He reasoned from this that, considering the frequency of genital tuberculosis in men, one would expect at least an equal frequency of peritoneal tuberculosis in men and women; therefore, he thought that peritoneal tuberculosis was probably secondary to tuberculosis of the Fallopian tubes in women, although it often seemed to be primary.

Some cases have recovered spontaneously; some have died of phthisis very soon after the operation.

Why recovery takes place after the operation is still a mystery. Ahlfeld⁴ reports a case of what appeared to be tubercular nodules on the peritoneum, where the patient died one and one-half years later of cancer of the uterus: at the autopsy the tubercles had disappeared, and only adhesions were found in their place.

We need more reported cases to be able to judge what proportion will be ultimately cured, but the immediate relief alone is sufficient to indicate the operation.

Reports of Societies.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

MEETING, March 7th, 1888. In the absence of the chairman of the Section, Dr. J. J. MINOT was, on motion, chosen to preside.

Dr. O. K. NEWELL read a paper on

THE SURGICAL USE OF HEBRA'S CONTINUAL BATH OR WATER-BED.¹

Dr. D. W. CHEEVER said: I am very much interested in this subject. I remember a good many years ago, hearing that the late Dr. Hamilton, of New

² Five months after the operation the patient remains perfectly well.

³ Cent. f. Gynecol., No. 45, 1887.

⁴ Cent. f. Gynecol., No. 46, 1887.

York, had treated some severe injuries of the foot in this way, with great success. Although I have never seen the apparatus used, I should think it might be very practicable. As happens to most persons who have been in practice a good while, I have seen a great many bad burns, and one in particular that I will mention as being very well adapted to this mode of treatment. The patient recovered, much to my surprise; I thought he would die. His entire back was burned from the shoulders down to the nates, and until he got some degree of strength, he was forced to lie for a good many weeks in bed on his face; a position in which it is very hard to be non-rushed, very hard to sleep, very hard to digest, very hard to have the natural functions of the body carried on properly. As soon as he could possibly do so, he was encouraged to get up, and after that he passed many hours a day standing. He could not sit, and would stand until wearied out, and then lie down on his face again. He eventually recovered perfectly, but was some months in doing so.

It seems to me that this was exactly the case in which such a bath would have afforded great relief. As I understand it, this patient could have assumed almost any position in the water, and without troubling his back. No doubt his recovery with this treatment would have been much more rapid. With the modern modes of heating hospitals it would seem as if the requisite heat might be kept up in these appliances without much trouble, from the steam pipes and the hot water, and it would need only a moderate amount of mechanical construction to make a nice water-bath for the limb or the whole body. I hope it may be introduced here.

DR. CHADWICK: When I was in Vienna, Hebra was treating certain skin diseases with the perpetual bath, and I remember seeing one patient who had been three years in the bath, who came out for a month, but went back again. I cannot remember the disease.

DR. NEWELL: I remember at the time that I was there that there was a marked case of Psoriasis Universalis in which the man looked as red as a boiled lobster. He was under water for a month or two. He was taken out and powdered with oxide of zinc, or something of the sort, and was then put back again.

DR. VICKERY: Are bed-sores treated so?

DR. NEWELL: It is exactly in such cases that the bath is of most use. Patients with bed-sores are floated in the bath and do not bear any weight at all on the sore.

DR. A. T. CABOT read a paper on

TWO CASES OF LAPAROTOMY FOR TUBERCULAR PERITONITIS.²

DR. J. W. ELLIOT followed with a paper on

A CASE OF TUBERCULOSIS OF THE PERITONEUM: EVACUATION OF ASCITES BY LAPAROTOMY: CURE.^(?)³

A considerable discussion followed the reading of these papers.

DR. G. W. GAY then presented a communication on THE TREATMENT OF FRACTURES OF THE EXTERNAL CONDYLE OF THE HUMERUS,⁴

and showed specimens, splints, etc.

DR. CHEEVER: Some years ago, Dr. Fifield called to my attention a mode of treating fractures of the external condyle which he had picked up from some French author and which he pursued for a while; but I believe he afterwards became convinced that although it was philosophically correct, it was not practical in its results. And that was to treat the fractures of the external condyle in the straight position, the same as you would treat fractures of the olecranon; the argument being that the extensors and the supinators which are attached in and above the outer condyle of the humerus are put in a state of relaxation by straightening the arm. Consequently, if the fracture was to be treated by relaxing the muscles, it could best be treated in the straight position. This was a very pretty theory; but it soon proved to be very fallacious, from the fact that whenever true fracture of the external condyle occurs the head of the radius necessarily travels with it in whatever direction the fracture goes. In a very large proportion of cases the radius is slipped up in front and held there; and consequently, when these cases are taken from the splint it is found that flexion is restricted by the head of the radius, precisely as Dr. Gay has described.

That being abandoned, we went back to the ordinary way of treating all fractures about the elbow joint, except those of the olecranon, with the internal rectangular splint. And here I would call to mind what Dr. Bigelow said in his lectures, and it was a very important direction; namely, always to go through the manipulation to reduce a dislocation of the elbow before you put on the internal angular splint.

In that way, of course you stand a very good chance of drawing all the displaced fragments into place.

I had supposed that, as a rule, when the ulna was displaced backwards, in these fractures, the shaft of the humerus must necessarily be broken off just above the condyles, in that familiar way which we know, when fracture of the humerus directly across the shaft above the condyles is not seldom mistaken for dislocation, or the dislocation for a fracture, (the deformity when you first see the patient being precisely similar), but if a case like this which Dr. Gay cites, when one fragment can be felt in place, proves that a different state can exist, then of course, we must look out for that.

I have had no experience in treating the arm at an acute angle. I have found, what I believe all authors agree to, that as to perfectness of results more depends upon the youth of the patient than upon anything else; and, as a rule children under puberty get pretty good results after fractures; and as a rule they get more and more stiffness as they approach adult years, after a break which fairly enters the elbow joint. The great advantage attending the use of ether I fully believe in. The precept of Dr. Bigelow, always forcibly to reduce a supposed dislocation, is also, it seems to me, a very important one.

Passive motion does not always do what you expect. A violent motion frightens the patient, and often leads him to run away from you; and, sometimes, if you are anxious about the case, you have to hunt him up, and see how he is getting on. Dr. Bigelow used to say that he was not much inclined to passive motion,

² Reserved for later publication.

³ See page 492 of the Journal.

⁴ See page 492 of the Journal.

on the ground that it lighted up trouble in the joint.

In a young child you can get good results, and they can be decoyed into passive motion by play-things, by carpenter's tools, by gimlets, by carrying weights, by various games, etc. You will find, I think, when you come to examine one of these stiff arms, when the child sets the muscles, that there are two sets of fibres, one the biceps, and the other the great supinator, which hold on as hard as possible. These two are solidly locked, and much passive motion is resisted. Of course, once in a while, we see a bad case where we give ether and try to break up adhesions, but very often this leads to a recurrence of inflammation.

To sum up, I should say, if the acute angle will give better results, I should be very glad to try it. It seems to me that after an early fracture in a young child it must be used with a good deal of caution so as not to interfere with the circulation in the hand. We know that if we use the right angle we have to watch it for the first day or two, on account of the effusion, and sometimes it is so great as to lead to thrombosis of the veins and interfere with the circulation. This position would be considerably harder for the circulation, and it seems to me would have to be watched very carefully for the first few days. I suppose Dr. Gay would agree with me that the number of cases that he has as yet had would not be enough to fully establish its safety.

DR. GAY: I would like to say that I do fully realize the importance of being careful at how acute an angle you place the arm. In the case of a child with a thin arm you can place the arm at a pretty acute angle and fasten it there without a splint. I think in adults you cannot do that. I put one case up under ether without a splint, and I waited until the patient waked up, but I was obliged to put it up at a less acute angle with a splint. I had no trouble at all, and the patient did not require an opiate. I think the moderate acute angle is a safe one and does not produce any more trouble than the right angle. Of course if there is much swelling, the splint must be put on loosely.

I bring up this method of treatment more as a suggestion than as a recommendation of its being better than any other. I have tried it several times, and think it worth bringing to your notice. I did not touch upon the treatment in the straight position, because it is much more difficult by passive motion to get flexion than extension, and I believe all surgeons are agreed that the right angle is the best position for the ankylosed arm.

DR. MIXTER showed

A PUNCH FOR THE REMOVAL OF POWDER-GRAINS IMBEDDED IN THE SKIN.

DR. NEWELL exhibited

A SPRING RETRACTOR FOR TRACHEOTOMY.

The instrument was specially useful in deep tracheotomies in children, where one was working without an assistant. It is passed around the neck and the hooks fitted into the wound and, by its natural spring, holds the flaps apart.

DR. F. B. HARRINGTON then showed

O'DWYER'S NEW INTUBATION TUBES FOR ADULTS, which were made of hard rubber instead of metal.

The following is a fuller account of the case of

WIRING THE FRAGMENTS FOR UNUNITED FRACTURE OF THE FEMUR,

(the specimen in connection with which was shown by the chairman, Dr. J. C. Warren, at the meeting of the Section on February 1st), than that given in the published report of that meeting.

The specimen had been presented to the Warren Museum by Dr. George H. Jennings, of Jewett City, Conn., through Mr. Allen Greenwood, medical student.

DR. WARREN said: The bone has firmly united, and in a depression at the point of union on one side the wire can be seen completely buried in the bone except at this point.

The peculiar interest of the specimen lies in the fact that the wire with which the bone was sutured was cut short and left in the wound. It is usually customary to leave the ends projecting so that they can be untwisted and the wire removed. This specimen shows that those who have adopted the former method are quite justified in so doing.

The following is Dr. Jennings's account of the case. I send this specimen with the accompanying history, thinking that Harvard might like to keep this evidence of the skill of one of her children in assisting Nature in her reparative process.

In June, 1875, the late Dr. Charles M. Carlton⁵ was called to see Mr. D., a man about fifty-five years old, with this history:

He was a ship carpenter; twelve weeks previously he fell from a steamboat wheel, a distance of about twenty-five feet, sustaining a fracture of the femur at about the juncture of the upper and middle thirds. He was treated by a "natural bone-setter" for twelve weeks by a straight posterior splint without extension. He then gave up the case, claiming that the bone would not unite.

Dr. Carlton was then called by the attending physician, a homoeopath, to amputate the limb. At the request of the family he took charge of the case.

The patient was much emaciated and feeble. At the seat of fracture there was free motion, the sensation given was as though there was an extra joint in the limb.

The patient was etherized and the fracture exposed by an incision made on the outer side of the limb. The fracture was oblique, the ends of the bone overlapping each other about four inches; they were united by fibrous bands. The parts were very vascular. The adhesions were broken up, the ends of the bone turned out of the wound and sawn off square. A hole was drilled through each end and a heavy platinum wire passed through the holes. The bone was then placed in position and the wire tightened; the wound was cleansed with a carbolic acid solution and closed with silk sutures. The limb was placed on a straight posterior splint.

The loss of blood was considerable, and the patient was almost in a state of collapse, but rallied with heaters placed around him in bed and stimulants given hypodermically.

During convalescence he was sometimes delirious, and twice removed the splint, causing a partial separ-

⁵Dr. C. M. Carlton was born in Waterford, Maine, April 28, 1838; he graduated in the class of 1861 at Harvard Medical School, served with honor during the war and practised surgery at Norwich, Conn. He was at one time President of the Connecticut Medical Society. He died of pneumonia, Dec. 30, 1886.

ration of the fracture. He recovered, with about one inch shortening, and worked at his trade. Death occurred two and one-half years later from pneumonia.

ALBERT N. BLODGETT, M.D., SECRETARY.

STATED meeting at 19 Boylston Place, Wednesday, March 14, 1888.

NATIONAL CONTROL OF MARITIME QUARANTINE.

The first business in order was the Report of the Committee appointed at the last meeting to take action on a pamphlet sent by the College of Physicians and Surgeons of Philadelphia, which was as follows:

BOSTON, February 15, 1888.

The Committee to whom was referred the report of a Committee of the College of Physicians of Philadelphia on the necessity of National control of maritime quarantine, respectfully report that, in their opinion, such National control is inexpedient.

HENRY J. BARNES,
CHAS. F. FOLSON,
SAMUEL H. DURGIN.

DR. H. J. BARNES: In presenting this report, Mr. Chairman, I will not attempt to give the reasons which governed the opinion of the other members of the Committee. For myself, after reviewing with care the address of the Committee of the College of Physicians of Philadelphia, and recognizing the deficiencies of inspection and provisions for care, at most of our ports of entry, which were shown by the Committee to amount to absolutely nothing in the way of protection, I cannot at the present time support the measures proposed by the Philadelphia Committee. The report contains no bill to be presented to Congress for enactment. We are, therefore, in doubt as to the scope of the desired legislation. Cumbersome machinery, falling into rust and decay from disuse, or destructive to commerce from too meddling activity, might be the fruits of our labor without full and complete knowledge as to what we are asking for. We may all favor general quarantine laws in the abstract, but it is doubtful if there exists sufficient unanimity of opinion to present a bill which would not invite defeat by exposing diversity of opinion as to how, when, and where the measures should be applied.

The legislation suggested by the report would probably antagonize the bill now before the House, presented by Dr. Davis, establishing a National Bureau of Health; and esteeming our internal sanitation of equal, if not of more, consequence than our maritime, and as this bill apparently covers both with an elastic authority only to be exercised where the exigencies demand, the success of this bill should not be jeopardized by advocating another. So far as I am informed, this bill places in central authority powers similar to those vested in the Local Government Board of Great Britain, the successful operations of which have proved sufficient to protect that country with far greater commercial relations than our own, from the importation of contagious diseases.

DR. BLODGETT: Does this Committee object to

the formation of any Government Board whatever, or only to the plan which was submitted in the pamphlet presented to the Society?

DR. BARNES: We discussed that, and considered only the plan in the pamphlet. We thought Dr. Davis's bill would be a wise one.

DR. S. H. DURGIN, another member of the Committee, who came in during the evening, was asked to give his views of the matter, and said: I don't know that I have anything to say in advocacy of any present change to National control. The Committee discussed the matter and came to the conclusion that we didn't need, at least here, any change. I don't know that I have anything particularly interesting to say to the Society. I should be very glad to answer any questions, if any member feels interested in the administration of the quarantine here. Some interest may have been aroused in the profession last week by the articles in the newspapers; if so, I would be very glad to explain matters.

In relation to the quarantine being administered by the National government, I don't see any advantage, myself, in such a course over that which we pursue now. I may be so near to it as to be blind to its faults, and may not be as good a critic as somebody a little farther off from the administration of the quarantine. I don't believe that our quarantine service is perfect, or that the accommodations are perfect. It would require a very large expense to make it such an institution as would enable us to meet an extraordinary emergency. But for such calls as we are likely to get, I think that we are fairly well provided, and I say this as the result of a rather long experience in handling the quarantine of our port.

We are not situated so as to expect an invasion of epidemic disease from abroad, as some of the other ports are. For instance, the difference between this city and New York is very marked. They have emigrants from sections which are epidemically or endemically infected with contagious diseases. We don't have them. It is a rare thing that we get any emigrant directly from these places. Some of the Southern cities are situated within a day or two of yellow fever infected ports. We are situated at a greater distance, so that in the case of a vessel arriving from Havana, one of the nearest ports for yellow fever, the period of incubation will be run out before they arrive here, except it be a steamer. We get very few passengers from there. They are mostly sailing vessels. The diseases may be contracted on board, as was the case with the small-pox patient the other day. In this case the exposure was about the Gulf Stream. We could not have prevented his exposure. This man who afterward took sick had been exposed for ten days to small-pox. The vessel was put through a course of disinfection; every rag of clothing, and everything which could be subjected to the same process, was subjected to steam at a temperature of 220° to 230° for fifteen minutes. Such things as cannot be treated by this are fumigated, and the deck of the vessel and the fore-castle are washed down with a solution containing one part in five hundred of corrosive sublimate. After a time the vessel was sent up town. The *Traveller* intimated that the vessel remained infected and conveyed the small-pox to this patient.

Our process is to examine every emigrant who arrives in Boston, and wherever there is any cause

for detention or disinfection it is carefully done. Formerly, vessels were kept forty days at quarantine, without any attempts at disinfection. Now we keep the vessel a short time, apply those means which are supposed to kill the germs of disease, and send the vessel away as quickly as possible.

Some ports of entry are wholly without the needful preparation for dealing with infected vessels, cargoes or passengers, and others are defective and for this reason some central order and direction may become useful when it can emanate from a properly constituted Health Bureau for the whole country.

DR. FOLSON said: There were two points which the committee had to consider. One was whether it was practicable for the United States Government to assume medical inspection of the various ports; and the second was whether it was the best way of doing it, if practicable. Before considering these questions the committee were obliged to acknowledge two facts. First, that there are only two cities where the medical inspection and disinfection, if necessary, is at all reasonably well performed; and the other fact was that in the other cities the sanitary conditions were such that the arrival of cholera or yellow fever would be attended with danger not only to those cities, but to the rest of the country.

First, as to whether it was practicable. I think it is absolutely out of the question. And for this reason: In 1878 or 1879 we had the most severe epidemics that the country has ever had, and the most fatal in large cities that has occurred since the great plague in London a little more than two hundred years ago. The mortality in Memphis in two summers was pretty nearly the same as that in the plague in London in four or five years. There was no time when the country had been more thoroughly aroused and when it was willing to take more efficient remedies. At the same time the medical inspection at New Orleans was very inefficient. They had no accommodations. In view of that fact, in 1879 the National Board of Health did what had never been done before. That is to say, during this very severe epidemic of yellow fever they surrounded the city with a cordon and disinfected every letter that went out of the city, and had every single train stopped a short distance from the city and the passengers transferred to another train, and absolutely prevented the disease from spreading anywhere.

The National Board of Health at that time was thoroughly in favor throughout the country. They had done something that had saved the commerce of the country from great derangement. There could not have been any more favorable circumstances to secure a national control of medical inspection than at that time. Under these circumstances it was thought worth while to make the attempt. The United States spent something like forty or fifty thousand dollars for buildings, and the whole of the Northwest made an effort to have the matter brought under national control, and yet the opposition was so great that the measure was defeated. If defeated under those circumstances it would be useless to attempt the thing at the present time. The medical inspection of New Orleans has now been carried on in such a way as to justify the opinion that an ordinary epidemic could be prevented. There is a committee in New Orleans that spends thirty thousand dollars every summer in keeping the city clean by ordinary

sanitary measures. There can be no question that it would be an absolute waste of energy to attempt the change. The matter would be so opposed from all parts that it could not be done.

The next point is whether it would be wise, if it could be done. In 1879 it might have been wise. The National Board of Health was at that time in the height of its power. It was, on the whole, wisely managed, and it would have been a good place to put such power if it should be placed anywhere. At the present time there is no place where it could be put. The United States Marine Hospital service has under control infectious diseases at our ports of entry, and I think that everybody would say that placing so great power in their hands would be as unwise as anything could be. These were briefly the reasons, as I understood them, why the committee voted as they did. The question of feasibility of medical inspection at different ports, how far it is worth while to do it, and how far it would benefit commerce, were questions which didn't come up, and on which we did not report.

On motion it was voted that the report of the committee be accepted and placed on file.

DR. JOHN A. JEFFRIES read a paper on

THE STERILIZATION OF MILK FOR INFANTS,

of which the following is an abstract:

He pointed out that the ordinary milk of the city was, when first supplied to the consumers, beginning to swarm with bacteria, and, by the time of being fed to the infants, often sour. To avoid this he had, adopting the custom of housewives, made a long series of experiments on the effect of steaming, and used with favorable results only steamed milk in the treatment of a number of cases of green diarrhoea of infants. To summarize, he had found that if the following rules were followed the milk was rendered practically sterile for several days. Stopper the flasks with cotton wool, and heat them in the oven for thirty minutes at a mild baking heat, or until the cotton becomes brown. Pour the requisite amount of food into the flask, and then place in the heated steamer for fifteen minutes.

The first rule was an advantage, but not of great importance; the second was both easily done and went to the root of the subject.

Any cooking steamer with a perforated false bottom and a snug cover would do, as the lower part of a Chamberlain's steamer. The heat must be sufficient to keep the water in active ebullition. The milk should be steamed when first received, not just before feeding, as the object is not only to give sterile food, but also fresh food, and to avoid the products of decomposition quickly formed in milk after the bacteria have become numerous.

DR. H. C. HAVEN said: I suppose that it is an admitted fact that the sterilization of milk is one of the most important advances that have been made in regard not only to the treatment of digestive disorders of infancy, the so-called summer diarrhoea representing them especially, but also to artificial infant feeding, the success or failure of which depends upon the presence or absence of gross disturbances of nutrition.

Years ago the whole blame for the failure of cow's milk was thrown upon the casein, because it did not coagulate in exactly the same way as woman's milk. It was assumed that that was the only trouble. It seems

to me that now it is necessary to bear in mind that there may be other causes besides the simple presence of bacteria to which to attribute the failure of cow's milk as a successful food, and make it the actual cause of disease, as it undoubtedly is in the summer diarrhoea of children.

It is undoubtedly of advantage to destroy the bacteria in the milk at the time of consumption, and in that way to prevent any further fermentative changes, but it seems to me that it is too much overlooked that the fermentative changes which have already gone on in the milk before the time of its sterilization and consumption by the child may have been sufficient to give rise to products of albuminoid fermentation which may be in themselves sources of disease which cannot be prevented by the sterilization of the milk at the time of the consumption. It seems to me a very open question whether it is the bacteria themselves which are the cause of disease (no specific bacterium has yet been discovered, to my knowledge), or whether it is some product of albuminoid fermentation, which is not only the cause of the diarrhoeas and digestive disturbances, but also the cause of the lack of success of artificial feeding. And unless that distinction is borne clearly in mind, it seems to me that we may attach too much importance to the sterilization of milk at the time of consumption. But I question very much whether, in artificial feeding or in acute diarrhoeal diseases the mere sterilization of milk which has already been subjected to the atmosphere for a number of hours, any very great practical benefit is going to be derived.

Again, the question of sterilization is one which has got to be considered from a practical point of view. I question very much whether, in the classes of society where artificial infant feeding, and the diseases which result from its improper employment most commonly occur, any plan of sterilization has been or can be devised which is sufficiently simple to insure its proper application by the ordinary unintelligent mother of the poorer classes. There is where we must combat the evils which arise from improper infant feeding, and until we can secure a milk which is gotten to the mother in the sterile condition, I question, I say, whether any practical benefit will be derived, although a very considerable benefit does come, undoubtedly, from such a plan as has been spoken of, if properly employed.

I have used one or another method for the sterilization of milk with apparently a certain amount of advantage in a number of cases, but I must confess that it has also given me a certain amount of disappointment. Its routine use at the West End Nursery failed to show any advantage, and I do not believe that until we can secure milk which can be made sterile at the time of production, can be kept free from the products of albuminoid fermentation, we shall have made any great advance.

Dr. T. M. Rortch said that Dr. Jeffries's paper is interesting and shows evidence of careful bacteriological work. There is, however, such a thing as making bacteriology too prominent in a clinical question. It makes little difference to us, when we are about to feed a baby, whether the food which has been sterilized remains sterile for days, provided it remains so long enough for the baby to drink it sterilized. The bacteria exist in large numbers in the baby's stomach, and the reason for giving sterile food is to destroy

the developed bacteria in the food and to copy from nature. I think that we in our ignorance should copy nature so far as possible. Woman's milk having been proved to be sterile, that is one factor which we may copy. Whether it is a factor which is going to be of extreme importance in the future, the future must decide. In feeding babies we have to take all the factors into consideration, and it is the sum total which gives us the result.

Now, admitting for the present that the sterilization of milk for infants is a good thing, and, so far as I can see, it probably will be proved to be so, we should adopt, of course, as simple a method as possible for the sterilization.

Professor Soxhlet, in Munich, has made a very careful study of this subject, and has published the result of his investigation on the sterilization of milk in the *Münchener Med. Wochenschrift*, No. 15-16, 1886. I have also received a letter from Dr. Caille, of New York, who studied with Professor Soxhlet, and who has recently read a paper before the New York Academy of Medicine on this subject, in which the same ground has been gone over, and he has sent me his results, which correspond closely with Dr. Jeffries's work. So far as I can see, the work of the bacteriologists shows very uniform results.

We, who engage in clinical work, must take advantage of these results. Dr. Caille's article will be published in the April number of the *Dietetic Gazette* for 1888. Dr. Jeffries's paper is valuable both in itself and as corroborating these results, and, of course, if they agree, we have certain facts to go by. As to the change in the color of the cream mixture, did I understand Dr. Jeffries to say that it began at once on exposure to the steam?

DR. JEFFRIES: I never saw any in which it did not take place. As soon as heated up, it commenced to turn brown. I could not say when it stops. I believe it is always present when the alkaline hydrates are boiled with sugar.

DR. RORTCH: My own work on sterilization was done in connection with my article on Artificial Feeding in the spring of 1887, and published later in the August number of the *Archives of Pediatrics*. The chemical analyses were made by Dr. Harrington. At that time it was recognized that the brown color was produced by the action of the lime-water upon the milk-sugar. What it is, I, of course, am not in a position to say. Whether it makes any especial difference whether it takes place or not, or whether it ever hurt a baby to drink the milk which was slightly colored in this way, I do not know; but I suppose that it does not.

In regard to the experiment that Dr. Jeffries speaks of, it was made with a cream mixture, which has to be changed according to the individual infant, as a rule. Sometimes it is successful with babies, and sometimes it is not. The reason that I especially spoke of it in my article was that the chemical analysis of this mixture corresponded more closely to the chemical analysis of the average woman's milk than any other that I have met with. That especial experiment was performed by Dr. Ernst. He placed in his sterilizer this mixture, and at the end of fifteen minutes it had not turned in color. He then placed it in the incubator, and found that it was sterile. Where the cream mixture was steamed for half an hour, it did change color. I have made experiments

myself since, and they entirely coincide with Dr. Jeffries's; that is, using the steamer and heating rapidly, I found that in ten minutes a certain change in the color took place. There is no doubt about it; the tubes show a decided change in color. As to whether it is neutral, acid, or alkaline, that, of course, can be determined by more delicate tests, perhaps, than test-paper. The paper which I used showed the mixture to be alkaline. I will present to the inspection of the Society the test-paper which I used, which, I think, is good. It makes a great deal of difference, of course, what test-paper is used. Will Dr. Harrington say what the results of the more delicate tests were.

DR. CHARLES HARRINGTON: I tested certain of the tubes which Dr. Rotch speaks of with turmeric paper, which gave a decided alkaline reaction, and also with the indicator phenolphthalein which also indicated that the sterilized milk was alkaline. It was not so alkaline as the milk that had not been sterilized. I notice Dr. Jeffries speaks of certain of these tubes having an acid reaction after boiling or steaming a solution of sugar with lime-water. We begin with an alkaline reaction, and it seems to me perfectly impossible to get an acid reaction. In fact, the very process of steaming, it seems to me, would prevent any acid formation. I have tested these solutions, and found them to be still alkaline. The alkalinity is, to be sure, somewhat reduced, which would indicate possibly a union of part of the lime with a part of the sugar. As to the color, I think it cannot be known by anybody what it is. It is one of the indefinite products generally spoken of as the brown products, which chemists know nothing about. It has been suggested that it might be due to caramel formation, but the temperature is not high enough for caramel formation, which is a result of dehydration. The test-paper which Dr. Jeffries used is, I think, open to very serious objections. The same paper which he uses, I find gives an acid reaction with distilled water and the ordinary service water, which, we all know, has a very faint alkaline reaction.

DR. ROTCH: There is one point that I am very glad Dr. Jeffries spoke of, and that is that while this mixture was decidedly alkaline before steaming, the alkalinity decreased after steaming; and that is an interesting point to me, because I have used this preparation a good deal in the last two years. For instance, in a lady who was partly feeding her baby with the breast and partly with this mixture, I tested the milk as it came from the breast, and found that it was slightly alkaline, and on testing the cream mixture I found that it was decidedly alkaline. After steaming, it was nearer the breast milk in degree of alkalinity.

I have not had an opportunity before of showing some nursing-tubes which I devised, not simply for sterilization of food, for that is only a part of the whole problem, but, recognizing that we should copy from nature so far as our knowledge goes, in cases where everything else has been tried and the fermentation still takes place, I devised these tubes in reference to the sterilization, as well as to the other factors. I believe that it is the quantity, as well as the quality, which will make a food agree or disagree, and I have, therefore, put in this factor. You can make the tubes correspond with the age of the child, using any food which you choose. They are made like test-tubes,

and have a round bottom, so that they can be easily washed — better than those which have angles. Having them in the shape of tubes, they can be sterilized, and they have a small hole in the side, to avoid the formation of a vacuum. I have also had a steam apparatus made, which is practically that which Dr. Jeffries describes. It is a covered pan with a perforated diaphragm, which stands upon legs and can be heated by a lamp below. The tubes simply stand in the steam. In order to get sterilized milk into the baby, I advise tubes of this kind, where a rubber nipple is used as in the nursing-bottle, and then a stout rubber cot is placed over the tube and the first nipple. It is then placed in the sterilizer, and all that you have to do to give it to the baby is to take the rubber cot off, and we have the milk swallowed sterilized, just as it is when it comes from the mother's breast. Whether that is of very great importance, I don't think we have determined. But we should copy from nature as far as possible. If nature's food is sterile, we should try to copy that sterility. If nature gives a certain amount, we should try to get that amount. If nature provides a certain amount of fat, we should try to introduce that amount of fat into our artificial food.

In regard to the Anglo-Swiss condensed milk, I have used it at the Infant Hospital. It varies in its analysis as do all the patent foods, and the last can which I had analyzed was decidedly deficient in fat. That can evidently was made up of skim-milk, and the per cent. of fat, instead of being about ten, was somewhere about seven, and was markedly deficient. Leaving out the other objections to the condensed milk, you can make up the proper amount of fat, by adding cream. I have sterilized condensed milk in the same way, and put in what I considered the proper amount of fat, and so far as the sterilization was concerned, it went very well indeed. The method of raising the fat was this, and I think it may be of some use to the profession when they wish to increase the fat in their artificial foods.

If you use a cream which is made by the centrifugal method, and which I hope in a very short time can be made with an almost exact per cent. of fat in it, you can take your hundred parts of condensed milk diluted 1 to 6 and make it almost exactly correspond to mother's milk, so far as the chemical analysis of the fat is concerned; for knowing the per cent. of fat in the diluted milk, and also in the cream, you can by simple rule of three add enough cream to obtain the requisite 4 per cent. You can take a half-teaspoonful or teaspoonful, or measure exactly in grammes, and have a certain proportion of fat in the mixture.

I stated in my article that it was best to sterilize for twenty minutes, and I think that is what bacteriologists agree to be the proper time to allow.

DR. E. G. CUTLER: I have had some experience with this method of sterilization, and certainly in my hands it has worked very well indeed. I noticed very early in the use of it the brown color which Dr. Jeffries has mentioned. At first I was, perhaps, somewhat apprehensive of it, and tried the sterilization over a second or third time. It happened every time, and finally I made use of the milk, and the child seemed to get along perfectly well. Since then I have used it a good many times, and have had no bad result whatsoever. The child would take it just as readily as any other milk. He speaks of the blowing

out of the rubber nipples which Dr. Rotch advocates. I have never had any trouble if they were placed carefully on and pinched a little to leave a certain amount of residual space so that it could distend a little. There might be danger where there was a lip, but in the straight bottles there has never been any danger in my experience.

In an ordinary bottle these same nipples, or similar ones, may be used without blowing out, provided the physician is careful to pinch up the rubber and blow out the water, and allow a certain amount of distension. With reference to this particular sterilizer that Dr. Rotch has invented, I have found some difficulty in keeping it heated with the alcohol lamp, so that I use an ordinary gas stove, or Bunsen burner, and find that it heats up very much quicker. I want to say one thing in reference to the centrifugal cream that Dr. Rotch speaks of. I found that the richest cream varied a great deal, and I have given up the use of it, because I found that I had to test each specimen every day, so that now I use the "strawberry cream." In my hands this has been more successful than the other kind. Otherwise I found that every day or two I had to go about and give directions about changing the amount of water. There is one question I should like to ask Dr. Jeffries, and that is in reference to the cotton stoppers. Do I understand that he advocates them in preference to the rubber nipples?

DR. JEFFRIES: These stoppers are regularly used in the bacteriological experiments. The glass is sterilized first, and then raised up to 150 degrees; at that temperature the stoppers would be blown out.

DR. CUTLER: I have several times had children who were eating ordinary mixtures of milk and water, and cream, for that matter, in various proportions in lime water, who have had more or less trouble with the bowels, and green stools—sometimes the motions would be creamy, with a good deal of green following or preceding—and I have had the cream carefully made and sterilized, and the child would get better, and the stools would look very well; and afterward they found it was so much easier to take care of the child that in several instances they made use of this method of sterilization. A sterilizer was improvised at one time at home by taking a pot and putting a cullender inside. It worked well.

DR. KOREN: I would be very glad to get Dr. Jeffries's account of the changes which occur in the boiled milk; I believe he prefers the steamed. What are those changes?

DR. JEFFRIES: I said that the changes are more in the boiled than in the steamed.

I recommended steaming the milk when it was first received, before the bacteria were very numerous. The brown color was spoken of simply as a matter of observation. I used the mixture myself in one case, and found no injurious effect from it. It is a great deal better to know that it is there and does not do any harm, than to think that it should not be there and be afraid of it. As to the stopper, we use that in the previous heating. I heat all my flasks first in an oven. To make it safe these must be heated first in an oven before the food is taken in, because the bacteria might get inside, and these stoppers are not heated each time. Then putting in the food you may sterilize them. It makes a great difference.

DR. ROTCH: I have been told by Dr. Ernst that the

steam kills the bacteria and not the germs; and that it does not make any difference, so far as the feeding of the baby is concerned, whether you kill the germs or not.

DR. JEFFRIES: There are a good many ways of looking at it. It depends upon how long you wish to carry the milk. Sometimes you wish to carry it several days; and then it is better not to have spores in it. Many times the germs are not killed. The germs of the infectious diseases we know nothing about, but if they are like those we know, then reasoning by analogy they are killed.

DR. ROTCH: We must reduce this question, of course, to a practical basis. We must feed the baby, and we wish to give the food without the germs getting into it which can easily be done by means of the rubber nipple and cot.

DR. JEFFRIES: The germs are forming spores constantly. Most of them are killed in the stomach, and that makes very little of them. But where the milk has been standing a long time these products are injurious to the infant, and by this arrest of spore formation we can prevent that putrefaction and stop those changes which make the child sick. It is also according to the theory that many of these infectious diseases are spread from the milk. If the flask is first heated we guard against that. The first heating in the oven is to make the thing systematic and complete.

DR. F. H. DAVENPORT: I would like to ask whether the simple milk alone turns brown, or only that to which the lime water has been added.

DR. JEFFRIES: The only place where I noticed the brown color was where milk sugar and lime water was added to the cream and milk making the so-called cream mixture; there we saw the brown color. That is the only place where the lime-water was used.

DR. DAVENPORT: I think it probable, in the heating of sugar with either acids or alkalis, that invert sugar is formed; and color is always developed under those conditions; and it develops, ordinarily, at the temperature of 80° C., so that probably boiling is sufficient for that purpose.

DR. JEFFRIES: There is one thing that I forgot to speak of, and that is the reaction. I used litmus paper imported from London. I merely noted the color, because I understood that there were other things that would do better. Two or three days ago one of these other specimens of lime water was tested with (?) which failed to show alkaline, I understand. I hoped Dr. Harrington would be able to settle the question whether it was acid or alkali. I don't think it is really known, but I hope we shall know in a day or two, as I sent Dr. Harrington one of the tubes.

DR. HARRINGTON: I endeavored to take the reaction, but it was too late, as it was putrid. I would like to ask Dr. Davenport if he can conceive the possibility of an acid reaction from boiling lime water and sugar.

DR. DAVENPORT: It is outside my experience. There is sometimes a little confusion about the reaction of milk, because the salts which give the reaction are the acid and neutral phosphates, and you may get an amphoteric reaction; that is, have at the same time both an acid and an alkaline reaction, according to the way you made the test. If you look at the litmus paper while it is wet it may appear red or acid, and if dry it may have become blue; that is, neutral or alkali-

line. And so fresh milk, with the litmus paper still wet, has an acid reaction, usually considered to be due to the free carbonic acid. As that escapes it becomes neutral, and then, as fermentation progresses, becomes gradually more and more acid.

DR. VICKERY: There is one question I would like to ask, although a little apart from the subject. There are two kinds of Anglo-Swiss milk. One is put up in Switzerland and one in England. I would like to ask which Dr. Rotch prefers. I, myself, have preferred that put up in Switzerland.

DR. ROTCH: I think that the one Dr. Vickery speaks of is the one I had examined, and although it was found to be made of skimmed-milk, yet it is probably to be preferred to that which is put up in England.

DR. HAVEN: It seems to me that that prepared in Switzerland is the better. In the Anglo-Swiss milk prepared in England there was more bacteria, and also they developed quicker. It seems to me that there is no comparison as to the relative value of the two milks, whatever may be their chemical composition.

DR. VICKERY: My reason for wanting to know is that this is the cheapest condensed milk for sale. It is desirable to know if it is as good as any other; and still more if it is the best. There is one thing about the hole in the bottle. When it is made at the top the milk is apt to run out. I have made a hole at the foot of the bottle, which is covered with a piece of India rubber, which, when the baby begins to suck, is moved off the hole by the nurse's finger, and does not give any trouble at all.

Adjourned at 10.15 o'clock.

PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

MARCH 10, 1888, the President, DR. WILLIAM L. RICHARDSON, in the chair.

DR. EDWARD REYNOLDS read a paper

ON AXIS-TRACTION FORCEPS, THE PRINCIPLES OF THEIR CONSTRUCTION, AND THEIR VALUE IN PRACTICE, WITH A DESCRIPTION OF A NEW MODEL.¹

DR. C. E. STEDMAN had always succeeded in delivery with ordinary forceps, and instanced two cases in which the head was high, wherein he had delivered by exerting traction far back against the coccyx: he might have operated with greater ease, however, with axis-traction forceps.

DR. HOSMER said that he had been practising medicine for over thirty years under difficulties which might perhaps have been greatly diminished by the use of axis-traction forceps; and he recalled cases in which such an instrument might have been used with great advantage. He had learned the value of traction far backward, when the head was high, and thought it an important addition to our facilities.

DR. BOARDMAN said there was a general ignorance in this vicinity of axis-traction forceps, and he himself had had very little experience with the instrument. As a rule he preferred version to forceps when the head was high; but he questioned whether, except in

expert hands, high forceps would not save more foetal life. Certainly with the head engaged and version ruled out, the axis-traction forceps has a useful application, and maternal soft parts may be the better saved by the improved direction of traction made possible by this instrument. The complicated character of most axis-traction forceps and the difficulty of their application was a great objection to their general use.

DR. BLAKE had always felt that with the ordinary forceps the force was applied at too long range from the point where it was desired, and he could now look back on cases wherein axis-traction forceps would have been serviceable. He had generally used Elliot's forceps, delivering with the patient on her side.

DR. J. P. REYNOLDS said that several years ago impressive testimony in favor of axis-traction forceps had been given by Ellwood Wilson, who two years before had spoken against the instrument. Dr. Wilson had based his change of opinion on his experience with axis traction in six cases, in which he thought he had saved foetal life by resort to axis-traction forceps.

DR. W. L. RICHARDSON said that Dr. Edward Reynolds had so fully explained the theory of axis-traction forceps that he could add nothing, except his own experience with them. He had only used Tarnier's original forceps, and in some cases had found a great deal of difficulty in applying them. A number of years ago he had believed very strongly in the superiority of high forceps over version, but as he had gained more experience in the Lying-in Hospital he had changed his mind, and now thought that in cases where interference was demanded, the head being at or above the superior pelvic strait, the operation of version was safer for both mother and child. The application of the axis-traction forceps, however, must be of value in cases where, from the condition of the uterus, the operation of version is either contraindicated or could only be done with an unwarranted risk to the mother. He had been struck by a remark contained in a manuscript lately received from Dr. Doléris, of Paris, to the effect that the Obstetrical and Gynecological Society of Paris has by a vote decided to hold to the former models of the forceps of Levret, Smellie, Simpson, Barnes, etc., believing that though the axis-traction forceps of Tarnier, Poullet, Breus, Braun, and Crozat may have some advantages, yet these are outweighed by their complications. The latest device from the application of axis-traction forceps is in the so-called Poullet-Levret forceps, by which the traction is applied by tapes passed through openings in the upper sides of the blades, and subsequently attached to the traction-handle by means of a steel rod, through the upper end of which the tapes pass. Dr. Richardson had had no experience with this last modification, but, theoretically, it seemed very ingenious and practical. The application of axis-traction, as suggested by Dr. Edward Reynolds, was very simple, and less likely to prove a vehicle for septic infection than most of the forceps now in use.

DR. HOSMER reported the following

CASE OF ACUTE MENINGITIS.

Notes of an autopsy made five hours *post mortem* March 8, 1887, by DR. J. A. MEAD: Bloodvessels of the pia and cortical substance injected, and clots in the vessels of the former. Both hemispheres presented a dull, glazed appearance, and their convolutions were

¹ See page 189 of the Journal.

adherent; between the two hemispheres, also, there was some adhesion. Fissure of Sylvius was closed. No tubercles at base of brain. No pus. Other organs normal.

The patient was nineteen months old, female. She had thirteen teeth, the last one cut being the left canine. In the summer of 1886 she had a diarrhoea, which, not very severe, was rather persistent. Otherwise the child had been a healthy one. During the night before her death she had been less quiet than usual, but her mental condition was perfectly normal. She was playful and bright until 6.30 o'clock, when there was a slight convulsive action. Consciousness was perfect until an hour later, from which time the symptoms became alarming. Death occurred at 12.30, six hours after the first significant symptom appeared.

Very early in the case laryngeal obstruction had become so marked that the family and neighbors supposed it to be an attack of croup, and with that idea sent for me. The absence of headache and of distinct nausea and vomiting should be noted. At 9 o'clock the temperature was 41.4° C. At 10 it had risen to 42° C., which is 107.6° F., a very high temperature. At 11 it had fallen to 41° C.

For a moment, the influence of some infection was suggested by the remarkable temperature which speedily attended a sudden and severe attack, but that suspicion was soon abandoned. That it was not extremely absurd is shown by a case reported by a German authority, in which scarlet fever was supposed to exist. While the appearance of the eruption was anxiously being waited for, death overtook the child. An autopsy made a diagnosis of acute meningitis.

Dr. C. E. STEDMAN spoke of the case of a child playing in the door-yard and who had had no previously observed symptoms, who was suddenly seized with convulsions and died: autopsy showed cerebrospinal meningitis.

Dr. HOSMER also spoke to the following query:

CAN UTERINE HÆMORRHAGE BE PRODUCED BY RENAL DISEASE?

Under this title I reported to the Society in June, 1886, the interesting case which suggested the foregoing question. That report may be found in print in the issue of the *Boston Medical and Surgical Journal* of 28th October, 1886. As a supplement thereto I wish to read the following note written to me by Dr. John W. Farlow, 20th May, 1887.

Apropos of the case of Mrs. B., I thought you might be interested in two cases reported in the *Revue des Sciences Médicales* for April, 1887, page 519. Trier reports two cases of women with Bright's disease, one forty-four and the other thirty-six years old, who entered the hospital for very profuse metrorrhagia. Both were very anæmic. One died in two days, and the diagnosis was not made until the autopsy. Both kidneys were affected with interstitial nephritis, and the heart was hypertrophied. The other patient presented all the signs of a sub-acute uræmia; and shortly before her death signs of pericarditis with exudation were discovered. She had nephritis both interstitial and parenchymatous, and the left verticle was enlarged. In both cases the uterus was healthy; at least presented no alterations capable themselves of explaining the metrorrhagia. The alterations were simply a slight thickening of the walls of the uterine arteries, of the same origin as that which existed in

the renal and cardiac arteries. In one case at least this arterio-sclerosis could be ascribed to alcoholism.

Dr. BOARDMAN asked Dr. Hosmer whether, in cases like the one reported the metrorrhagia was not due to cardiac disease, which latter may have ensued from the renal affection.

Dr. HOSMER believed that in cases of hypertrophied heart consequent upon kidney disease the hæmorrhage was due to changes in the vessel walls rather than to the cardiac affection.

Dr. Hosmer reported the following observation made in 1879: I was in attendance upon a young primipara. Having decided to use forceps, while a portion of the uterine neck still remained below the brim of the pelvis, I carried my finger within the os as far as possible, and swept it about the head. A full finger's length from the external os, the position of the internal os, as I suppose, was indicated, by a distinct projection which occupied the whole circumference of the organ, and without inequality at any point. Its edge was firm, sharp and well defined. Its section would be represented by an equilateral triangle. The amount of its projection was estimated at 8 millimetres; that is, about one-third of an inch.

HYDATIDIFORM MOLE.

Dr. BLAKE reported the following case, and Dr. W. L. RICHARDSON, at his request, exhibited the specimen:

Woman, twenty-six. Married two years. Five months after marriage had an abortion at third month; doctor called it a false conception, which means a blighted ovum.

Menstruated regularly for nine months. Last May menses ceased, and she supposed herself pregnant from that time. She states, however, that for several months following May 1st there was a very slight appearance, merely a stain, at menstrual periods till last September. Since that time until last Friday no bleeding of any kind. On Friday she had a severe hæmorrhage of a peculiar character, as if the blood was mixed with water, and accompanied with quite severe pain. Both ceased, however, and there was no recurrence till Thursday morning. On Wednesday she called to engage me to attend her in labor, which she expected soon.

The history as above, together with her size, which was not more than between the fifth and sixth month, led me to examine her per vaginam. I easily made a diagnosis between the condition found and placenta previa. The following morning I was sent for, as the pain and bleeding had recurred. I dilated the os with my hand, and after a tedious time succeeded in removing the entire mass. There was but little hæmorrhage. Woman has since done perfectly well.

AMERICAN MEDICAL ASSOCIATION. CINCINNATI, OHIO.

GENERAL SESSIONS.

FIRST DAY. — TUESDAY, MAY 8, 1888.

At eleven o'clock, A.M., the meeting was called to order by Dr. W. W. DAWSON, Chairman of the Committee of Arrangements, in the Music Hall. Prayer by Rev. R. A. GIBSON.

Dr. Dawson introduced Hon. AMOS SMITH, mayor

of the city, who delivered a most felicitous address of welcome.

The address of the mayor was followed by that of welcome by Dr. C. G. COMEGYS, who, as one of the oldest and most distinguished practitioners of Cincinnati, added the greeting of the profession to that extended by the mayor. The following were the opening sentences:

"On the part of the medical profession of this city I am happy to welcome you to Cincinnati, and to assure you that we, with all of the citizens, feel greatly honored that you have selected this, the most central city of the nation, for this annual congress. Twice before, to wit: in 1850 and in 1867, the Association has held its annual councils here, and your professional brethren and the people cordially united to make those occasions encouraging and profitable.

"These large assemblies of medical men, in increasing numbers every year, prove undubitably that the value of the Association is no longer a question. To say nothing of the scientific discussions involved, it is clear that the gatherings of the Association give immense satisfaction to all. It is, certainly, a great pleasure for men who are engaged in common duties and modes of life in widely separated areas to be thus brought together for the establishment of acquaintanceship and friendship that promote community of action for a higher performance of their beneficent work among the people."

ANNUAL ADDRESS OF THE PRESIDENT,

DR. A. Y. P. GARRETT, of Washington, of which we publish the following extracts.

"... In casting about for a subject, concrete in its nature and directly useful in its application, I have determined to submit for your consideration a few practical reflections upon the mission of the American Medical Association.

I am especially moved to select this subject at this time by the fact that at no period since the formation of the American Medical Association have its enemies been so bold, so reckless, and so unscrupulous in their efforts to destroy its influence and power with the medical men of this country.

The paternal relation held by this organization to the entire medical profession of the United States imposes upon it duties and responsibilities of the gravest character. It stands out before the world as the chosen custodian of all that pertains to the preservation and advancement of professional interests, as well as to medical science *per se*; it is intrusted with the delicate and difficult task of elevating and maintaining the medical character of this country upon the highest moral and intellectual plane.

Taking a retrospective view through the almost half-century of its existence, we have no reason to be discouraged when we consider what has been accomplished; indeed, we have cause for congratulation as we recognize the many evidences of progress due directly to its influence, important results which could only have been achieved by combined and co-operative effort. The crystallizing at its very birth of the hitherto segregated elements of medical strength into one compact organization gave to it a power and authority recognized and felt by the entire medical profession of this country.

But while we may well feel gratified by a contemplation of the fruits of our labors in the past, it is obviously important that we should not be flattered into the belief that we have accomplished our mission, and permit ourselves to lapse into supine indifference with regard to the pre-eminent important object which yet remains to be worked out, I trust, through the instrumentality of this body. I refer, gentlemen, to a radical and thorough

reform in the present system of medical education of the United States—the subject which, at this moment, presses itself more urgently than all others upon our attention.

It is but natural that those of us who have at heart the true interests of the medical profession, and who desire to encourage such progress and effect such reforms as must permeate and influence each section of our country, should make every endeavor to elevate our system of medical education to a standard equal in dignity and attainment to that which obtains in Europe, and hopefully look to this great representative body as the only central, dominating power through which such reforms are to be accomplished and perfected.

Our annual meetings must not be regarded solely for the purpose of considering the science of medicine either in its theoretical or practical aspect and supplemented by the pleasures of social intercourse. While we have ample cause to be gratified with the rapid progress made by some departments of medicine in this country within the last decade under the direction and stimulus of this association, we are still confronted by the fact that very little has been effected in the direction of a general reform in the medical schools.

We all know that this subject of medical education and medical license has been an almost endless theme for discussion, coeval, indeed, with the establishment of medical schools in America, and more particularly has it been earnestly and ably considered since the organization of this association; yet the question still presents itself, What can the American Medical Association do to further raise and promote a higher standard of medical education in the United States, to curtail the number of medical schools, and thereby gradually restrict to a conservative limit the annual hosts of graduates turned loose upon the public by those institutions? It will be borne in mind that in order to effect these desirable ends the initial step must be taken by this body in some mandatory form—experience has demonstrated that separate state societies and individual college regulations looking to such reformation have so far proved conspicuously futile. For a long period all measures brought before this association having for their object an interference with or material modification of the systems pursued by the medical colleges were met by a determined and successful opposition on the part of those members who represented such institutions.

So manifest did it become that no important change could ever be effected in this direction while these schools were permitted to be represented as such in this body by their own officers that an amendment to the constitution was adopted abolishing this feature of representation in order, as it was hoped, that the proceedings of the association might not be trammelled or embarrassed by the misguided efforts of such delegates.

Whilst the purpose and intent of this move was, as already stated, to free the association from the predominant power of the schools and permit it to legislate in a fair, unprejudiced and conservative spirit upon this important question, it has so far unquestionably failed to do so. It occurs to me that an explanation of this may be found in the fact that a large proportion of those who now attend our annual meetings are directly or indirectly connected with medical institutions, and no doubt are to a large extent, unconsciously, perhaps, influenced in their conduct on this floor by the supposed interests of their respective schools.

While it cannot be denied that there are medical colleges in this country unsurpassed by those of Europe in their essential appointments and facilities for the education of medical students, the equally undeniable fact remains that we fall far behind them in the systems of study pursued.

These views were elaborated and illustrated at some length, and led up to the following conclusions:—

Entertaining the views above expressed, based in part upon these tabulated expositions, and inspired by the hope of initiating some practical move in the direction of educational reform, I respectfully submit for your consideration the following suggestions:

Proposition I. That a standing committee, to be called a committee on legislation, be appointed for each State, Territory, and the District of Columbia, to consist of five members of the medical profession in good standing, three of whom shall have no official connection with any medical school or college, whose duty it shall be to carry out as far as possible the following instructions:

First. That each one of said committees, or a majority thereof, shall attend the sessions of their respective legislatures, or from time to time as their duties may require, for the purpose of using all honorable means looking to the reduction of the number of medical schools in the United States, and a consequent diminution in the annual number of medical graduates; that as a practical measure to this end they urge the passage of a law requiring that in the future granting of charters for creating medical schools there shall be a clause in every such charter requiring that all schools or colleges thus created shall demand a full term of four years' study before granting a diploma to any student thereof, and that no student shall be admitted to matriculate who has not passed a satisfactory examination, both oral and written, in the ordinary branches of academic study; and, further, that any college failing to show a greater number than fifty matriculates annually for three consecutive years shall forfeit its charter and be abolished.

Second. That they use all diligent effort to secure an ordinance creating in each State and Territory where no such board at present exists, and the District of Columbia, a board of medical examiners, which shall have no connection with any medical school, and which shall be required to examine all applicants for license to practice medicine in their respective States, Territories, and the District of Columbia; and that any person who may be detected in practicing any branch of the healing art without a license granted by said board shall be subject to such penalties as the law may provide. That this committee may be authorized by statute to select and nominate to the governors of the States, Territories, and the District of Columbia, seven competent and learned members of the medical profession to constitute said board of examiners, who shall have the exclusive power to issue licenses to practice the art and science of medicine and surgery.

Third. That the chairman of said committee of five be required to submit at each annual meeting of this association a report embracing a full statement of what has been accomplished by each.

Proposition II. That the faculties of the several medical schools within the limits of the United States be once more urgently requested to call a convention at some central point for the purpose of consultation and adopting some general and uniform system of medical education more comprehensive and rigid in its requirements, and more in accord with the spirit of the age and the advanced progress of medical science, suggesting a four years' term of study, the requirements of a preliminary education, including some knowledge of the classics.

That any college or school which shall refuse to enter into such an arrangement as may be decided upon by said convention shall be excluded from all connection with the American Medical Association, and its alumni not recognized as members of the regular profession.

I am aware that these suggestions embrace some very radical and seemingly impracticable changes; but as they point, in my judgment, to the right direction, I trust that they may not prove to be seeds sown upon barren soil. Be that as it may, I shall at least enjoy the consciousness of having honestly, conscientiously, and fearlessly met the great and pressing issue of the day within the domain of our profession, and of having ex-

cuted, to the best of my ability the most important duty imposed by the responsible position to which you have elevated me.

On motion of Dr. W. W. Dawson the address was referred to Committee on Publication.

Dr. N. S. Davis presented a proposition on behalf of a number of gentlemen from various sections, that, inasmuch as a larger number of papers are to be read before the Sections than can be well disposed of in the time assigned to their sessions, be it resolved that Sections so desiring may meet at eleven o'clock, A.M. for their special work. Seconded by Dr. Reynolds, of Louisville, and carried.

Letters of invitation to the visiting members were received from the Chamber of Commerce and the Technical School.

SECOND DAY. — WEDNESDAY, MAY 9TH.

Opened with a report of the Committee of Arrangements.

ADDRESS ON GENERAL MEDICINE,

by PROF. ROBERTS BARTHOLOW, of Philadelphia.

Dr. HOLLISTER, of the Board of Trustees for the publication of the journal of the Association, submitted the following report: Weekly circulation, 4,572; receipts for year ending March 31, 1888, \$11,897.98; disbursements, \$16,261.47. Increased receipts, however, exceed increased disbursements, so that the journal is self-sustaining, and a source of revenue to the Association. It is proposed to enlarge the editorial corps. It is requested that the Association shall place at the command of the editor-in-chief the exchanges of the *Journal*, references and book and monographs for review.

Dr. Wood read the report of the Committee on Dietetics, and Dr. FRANK WOODBURY that of the Sub-Committee on Infant-Feeding, to the following effect:

REPORT OF SUB-COMMITTEE ON INFANT-FEEDING.

Your Sub-Committee on Infant-Feeding respectfully reports that it has only had the subject under consideration for about two months, and during this time it has opened correspondence with some of the leading authorities both in this country and in Europe, upon the very important questions submitted to it, especially with reference to the proper diet of infants. Though not prepared to make a final report upon the subject at present, it believes that some facts have been elicited which are valuable and which are of sufficient interest to bring before this Association.

Thus far, replies have been received from Dr. Eustace Smith, of London; Dr. J. Lewis Smith, of New York; Dr. Victor G. Vaughan, of Ann Arbor, Michigan; Dr. George F. Rohé, of Baltimore; Dr. F. Forchheimer, of Cincinnati, and others to whom we desire to return thanks for their assistance and courtesy. (The correspondence and replies to queries submitted are appended to this report.)

The leading facts thus far obtained may be very briefly stated as follows:

(1) In the case of an infant, or a child under ten months of age deprived of breast-milk, the artificial substitute provided should be made to correspond with human milk as closely as possible, both in its chemical constitution and in its physical characters.

(2) Fresh, unsalinated cow's milk, when properly prepared is an acceptable substitute for breast-milk. But since the curd of cow's milk coagulates in a heavy, dense mass, while breast-milk curd is light and flocculent, some expedient must be resorted to in order to make the former resemble the latter, so that the digestive powers of the infant shall not be unduly taxed. The curd of cow's milk, according to Dr. Eustace Smith, as a rule traverses the infant's alimentary tract and may be found unchanged in the fecal discharges. It is, therefore, a constant source of irritation, and often gives rise to diarrhoea and entero-colitis. One of the most decided advances in dietetics, in modern times, is the preparation of cow's milk with the aid of digestive agents, as in the method recommended by Professor Frankland. In this method the curd of a por-

tion of the milk is first peptonized by fresh calf's rennet, and to this is added a portion of fresh milk, after heat has been applied to check the process and to prevent complete predigestion; some milk-sugar is finally added, and thus a mixture is obtained which closely approximates human milk in its chemical composition. It has, moreover, been found to serve as an efficient substitute, where the mother's milk is of poor quality, is inadequate in quantity, or is entirely wanting. The special feature of this method is the peptonizing of only a part of the casein, with the employment of heat at a certain stage to arrest the process so that the food shall not be completely digested. The addition of the carbo-hydrate (milk-sugar in this case) is necessary, in order that the food shall closely resemble human milk. The employment of stale, foul-smelling, partially decomposed digestive ferments, for the purpose of comparing cow's milk for infant's food is condemned. The necessary skill and intelligence required to insure uniformity of result for the extemporaneous peptonizing of milk rarely is to be found in the household, and where this process is adopted, the experiment often turns out to be unfortunate and injurious to the child.

(3) As the rule, raw starch is inadmissible in the diet of young infants, because the digestive powers of the infant are rarely sufficiently active to convert crude starch into a soluble form. The plan advocated by some, of adding starch to the milk in order to mechanically break up the curd, is unphysiological and very objectionable. The products of the complete digestion of starch are glucose and saccharose (maltose), and these, in various forms, have been recommended to be used as additions to the milk, under the name of "Liebig's" foods. When in excess, these substances cause diarrhoea, and do not sufficiently nourish the child. Dr. J. Lewis Smith speaks favorably of dextrine, which is a partially digested starch, as a good substitute for glucose and saccharose in such artificial foods. The fact cannot be too strongly insisted upon, which is taught both by clinical experience and by physiological investigation, that the food of either infants or adults, except in special emergencies, should never be fully pre-digested, for fear of permanently weakening or destroying the digestive functions of the stomach.

(4) A great part of the large mortality of infants in all our cities is due to the bad quality of the milk supply, particularly that going to the poorer classes. Professor Vaughan declares that many deaths from so-called cholera infantum are really caused by milk containing tyrotoxin. Authorities are almost unanimous upon the point that in large cities, at least during hot weather, all milk for the nursing-bottle should be boiled several times a day in order to destroy ferment-germs. It is better, at such time, that the food should be freshly prepared for each feeding. In some cases, owing to the variability in the quality of the milk-supply, it may be advisable to resort, for a short time, to condensed or to evaporated milk; in either case diluting and adding cream, or an equivalent soluble carbo-hydrate, in order to make an artificial breast-milk. Desiccated partly peptonized milk, in the form of a milk-fool, containing partly converted starch, (soluble starch, dextrine, and a small proportion of lactose) is a convenient (and when well-made, a very efficient) substitute for the mother's milk.

(5) Where the child is a premature birth, or is feeble from other causes, as great care should be observed in preparing its food as in prescribing its medicine. Experience has demonstrated that success in infant-feeding is dependent upon the ability to individualize the patient, and to select the proper food for each case. For very delicate infants the mother's milk is often found not only inadequate to properly nourish the child, but also positively injurious. This is generally admitted where some obvious dyscrasia exists, as the tuberculous or syphilitic. It is for such feeble infants that artificial mixtures can be made which will agree with the weak digestive functions and satisfactorily nourish the child.

In conclusion, your Sub-Committee would direct attention to the remote and far-reaching effects of the mal-nutrition resulting from improper feeding in early life, to be witnessed in chronic invalids or in premature death of the individual, and to the inevitable physical degeneracy threatening the race where the principles of infant dietetics are neglected. In view of the importance of the subject, the Sub-Committee respectfully asks to be continued in order to further investigate the matter, and to report to the next meeting.

DR. SAYRES offered a resolution that the Committee on Diet be continued, and empowered to enlarge its number, and that the Committee of Arrangements be authorized to give its work a proper place in the programme of the next meeting.

Dr. Sayres accepted as an addition to the resolution, "That the Committee is hereby instructed to present a report at the next meeting of the Association, embodying the general principles to be observed in a rational system of dietetics." Carried.

DR. N. S. DAVIS called attention to three amendments offered at the last meeting.

First amendment, to Section II of Constitution, relating to membership. The substitute proposes that members, by application, shall consist of such members of State, county and district societies as shall make application in writing to the Treasurer, accompanied by a certificate of membership in good standing of their society, signed by its president and secretary, and the annual dues, \$5.00. Such a member shall have all the privileges of a permanent member. Carried.

Second amendment, to Section V. That the Board of Trustees shall consist of nine members, three members to be elected every year, and term of service three years. It shall be the duty of the Secretary of the Association and the various Sections to furnish the Board with all proceedings in their departments. The Board shall have power to appoint the editor, pay salaries, etc. Carried.

Third amendment, which is to supersede the first clause under the head of Standing Committees: "Delegations from each State shall choose two members, registered at the meeting to act as representatives upon the Nominating Committee. At the first election one shall be chosen for one year, the other for two years, and thereafter one member every year, term of office being two years. The duty of the General Committee shall be to meet at the place of and on previous to the meeting of the Association: they shall select Chairman, Secretary, and other general officers, and such sub-committees as will facilitate the proceedings of the Association. If any member fail to be present, the Chairman shall select a substitute from the delegation of his State present at the meeting.

After considerable discussion, an amendment by DR. MURDOCH, of Pennsylvania, that the report be recommitted to the Committee, and amended by DR. JOHNSON, that it be made the special order of business at 12 o'clock, Thursday, was carried.

The Nominating Committee was then announced.

THIRD DAY.—THURSDAY, MAY 10TH.

Opened by the Chairman, DR. KARNETT.

A resolution was offered by the Kansas State Medical Society, denouncing the practice of advertising proprietary medicines in newspapers and religious journals, and the endorsement of editors, both secular and church. The resolution was, on motion, indorsed by the Association.

An invitation from the Philadelphia delegation to the American Medical Association, to hold its next annual meeting in this city, was received.

Committee on Nominations reported as follows:

President, Dr. W. W. Dawson, of Ohio; First Vice-President, Dr. W. L. Schenck, of Kansas; Second Vice-President, Dr. Frank Woodbury, of Pennsylvania; Third Vice-President, Dr. H. O. Walker, of Michigan; Fourth Vice-President, Dr. J. W. Bailey, of Georgia; Treasurer, Dr. Richard J. Dangleison, of Pennsylvania; Secretary, Dr. Wm. B. Atkinson, of Pennsylvania; Librarian, Dr. C. H. A. Kleinschmidt, of the District of Columbia.

Trustees to fill vacancies: Dr. E. M. Moore, of New York; Dr. J. H. Hollister, of Illinois; and Dr. J. M. Toner, of the District of Columbia.

Vacancies in Judicial Council filled by Dr. W. A.

Phillips, Kansas; Dr. A. M. Pollock, Pennsylvania; Dr. W. C. Van Bibber, Maryland; Dr. J. F. Hibbard, Indiana; Dr. Chas. S. Wood, New York; Dr. J. McF. Gaston, Georgia; Dr. W. H. O. Taylor, New York; Dr. Geo. L. Porter, Connecticut.

To deliver the address on General Medicine, Dr. Wm. Pepper, of Pennsylvania; on Surgery, Dr. P. S. Conner, of Ohio; on State Medicine, Dr. W. H. Welch, of Maryland.

One member of the delegation from each State was chosen to act upon the Committee on State Medicine, and another to act upon the Committee on Neurology.

In case the gentlemen appointed to deliver the general addresses should be unable to serve, a Committee consisting of Drs. J. B. Hamilton, Wm. Brodie, and A. Garcelon were appointed to select a substitute.

Newport, R. I., was chosen as the place of meeting for the Association, on the first Tuesday in June, 1889. Dr. H. R. Storer, of Newport, was elected Chairman of the Committee of Arrangements.

Dr. E. M. MOORE, of Rochester, delivered the address on General Surgery, in which he reviewed the progress of that department of medical science from the time of Hippocrates to the present day, dwelling especially upon the astonishing benefits derived from antiseptics. The paper was very interesting from a historical point of view.

The report of the Committee on Rush Monument reported slow progress, and that the available funds now amounted to \$709.00. There is promised (but not as yet paid) by the Pennsylvania State Society \$100.00, and by the Michigan State Society \$100.00. Funds are deposited in Riggs & Co.'s Bank in Washington, D. C. Report referred to Dr. Garcelon, of the Auditory Committee.

Treasurer's report read, showing receipts for year, \$25,649.90; disbursements, \$23,242.07; balance on hand, \$2,407.83.

Librarian's report received, stating that 7,500 volumes, representing 2,850 titles, were in possession of the Association.

Dr. N. S. DAVIS called for the consideration of the following amendment, which had been made the special order of to-day's session:

The General Committee or Council shall be composed of *two members* from each State and Territorial Medical Society, etc., entitled to representation by delegates in the Association, and from the Medical Departments of the U. S. Army, Navy, and Marine Hospital Service. They shall be chosen by the members registered and present at each annual meeting, from each State, Territory, etc., and from the Medical Corps of the U. S. Army, Navy, and Marine Hospital Service, acting separately, on the third day of each annual meeting; each delegation reporting the names of the members chosen to the Permanent Secretary of the Association on the same day, that they may be announced by him at the opening of the morning session of the fourth day. At the first election each delegation shall choose *two* members of the General Committee, one of whom shall serve *one* year and the other *two* years, and at each annual election thereafter, one member shall be chosen to serve two years, thus making the term of office of members of the General Committee *two* years. It shall be the duty of the General Committee, thus constituted, to organize by choosing annually a Chairman and Secretary, and such sub-committees as may be found necessary to facilitate the work that may be assigned to it; to meet annually at the place and on the day preceding each annual meeting of this Association, and as often during that week as may be necessary; to nominate, on the third day of each annual meeting, all the general officers of the Association (none of them shall be members of its own body), the members of the Committee of Arrangements, the Committee on Neurology, seven Members of the Judicial Council, and three members of the Board of Trustees for Publication for election by the Association; to recommend the place and time of holding the next annual meeting; and to consider and report upon all subjects that may be referred to it by vote of the Association. The

presence of one-third of the whole number of members elected to the General Committee shall constitute a quorum for the transaction of business. If, at any annual meeting of the Association, it shall be found at the close of the General meeting of the first day that a quorum of the General Committee is not present, it shall be the duty of the President and Permanent Secretary to fill the vacancies in the Committee temporarily by selections from the lists of delegates registered as present from the States to which the vacancies belong.

Dr. Davis moved to lay the amendment on the table until the next annual meeting, subject to final action at that time. Carried.

Dr. N. S. DAVIS offered an amendment relating to the affixing of names to the Constitution and Regulations of the Association, and that it be laid upon the table until the next meeting.

Dr. KELLER, of Arkansas, offered the following resolution: "That in future each delegate or permanent member shall, when he registers, also record the name of the Section, if any, that he will attend, and in which he will cast his vote for Section officers." Carried.

Dr. DALY moved to rescind the motion carried at yesterday's meeting, in reference to fixing the time of Section meetings at 11 A. M. Carried.

Dr. BRODIE moved, that hereafter the Committee of Arrangements be instructed not to provide space for pharmaceutical and surgical instruments and book displays at the meeting of this Association.

Met with decided opposition, voiced by Drs. QUIMBY, LUTZ, WOOD, JENKINS, and SCHWAB. On motion, the resolution was tabled.

Adjourned.

Officers elected in the various Sections:

Practical Medicine, etc.: President, Dr. F. C. Shattuck, Massachusetts; Secretary, Dr. G. A. Fackler, Ohio.

Surgery: President, Dr. N. P. Dandridge, Ohio; Secretary, Dr. W. O. Roberts, Kentucky.

State Medicine: President, Dr. J. B. Lindsay, Tennessee; Secretary, Dr. S. Armstrong, Massachusetts.

Ophthalmology, Otology, and Laryngology: President, Dr. G. E. Frothingham, Michigan; Secretary, Dr. G. C. Savage, Tennessee.

Diseases of Children: President, Dr. J. A. Larabee, Kentucky; Secretary, Dr. C. J. Jennings, Michigan.

Medical Jurisprudence: President, Dr. W. Kiernan, Illinois; Secretary, Dr. Evans, Maryland.

Obstetrics and Gynecology: President, Dr. W. H. Wathen, Kentucky; Secretary, Dr. A. B. Carpenter, Ohio.

Dentistry: President, Dr. F. H. Rehwinkel, Ohio; Secretary, Dr. E. S. Talbot, Illinois.

(To be continued.)

—The *Cincinnati Lancet and Clinic* thus translates two epitaphs from *Le Parnasse Hippocratique*, a collection of medical rhymes, which is just now amusing the Parisian doctors:

ON CIVILE, LE LITHOTOMIST. — BY DR. MOTET.

Here, where the dead are laid,

In this cemetery lone;

No monument on his grave's displayed,

For he'd rise and crush the stone.

ON VELPEAU. — BY DR. PETER.

Here lies penurious Velpeau, who

A surgeon was in days of yore;

He'd skillfully cut men in two,

He'd cut a farthing into four.

THE BOSTON
Medical and Surgical Journal.

THURSDAY, MAY 17, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

**THIRTY-NINTH ANNUAL MEETING OF THE
AMERICAN MEDICAL ASSOCIATION.**

THE annual meeting of the American Medical Association, held in Cincinnati the past week, was an industrious and harmonious occasion. Some 1,500 delegates were in attendance, of whom the large majority, of course, were from the West and South. Philadelphia sent a considerable deputation, and Boston was better represented than of late years. New York names were comparatively conspicuous by their absence.

The General Sessions were not marred by any wrangles over codes of ethics or organizations of Congresses. The Sections brought out some good work, and some of very exceptional value and interest. In the latter category we must specify Dr. N. Senn's presentation of "Rectal Insufflation of Hydrogen Gas as an Infalible Diagnostic Measure in Ascertaining the Existence of Visceral Injury of the Gastro-Intestinal Canal in Penetrating Wounds of the Abdomen."

Dr. Senn's experiments and conclusions are likely to earn and to deserve the appreciation and gratitude of surgeons who may in future be called upon to deal with the perplexing class of cases which he has been studying.

The paper presented by Dr. V. C. Vaughan, of Ann Arbor, before the Medical Section on the Etiology of Typhoid Fever was also of unusual interest. Dr. Vaughan took advantage of an epidemic of typhoid fever in northern Michigan to examine the water-supply of a family in which thirteen or fourteen members had the disease. The characteristic bacillus was found in the water, was cultivated, dogs were inoculated with the cultures, and there resulted a disease resembling typhoid fever as known in man, in the febrile movement, the clinical symptoms and the pathology. One of the dogs died of perforation of the intestine. If Dr. Vaughan's experiments and observations are substantiated and supported, conclusions of the utmost importance as to etiology and possibly as to treatment must result. Dr. Vaughan was disposed

to explain previous failures to inoculate the lower animals with the disease to the use of bacilli taken from the body and not from external media, as water.

The president of the Association, Dr. A. Y. P. Garnet, of Washington, devoted himself in his address to a consideration of the mission of the American Medical Association. The immediate and most important mission, he thinks, should be a regulation of medical education and the granting of medical degrees. The means which he proposes are set forth in our report of the general sessions.

Dr. Comegys, Chairman of the Reception Committee, in his address of welcome on the part of the local profession, gave an interesting sketch of Drake and Dudley, pioneers from the second decade of this century in medical practice and medical education in Cincinnati and Lexington, Kentucky. He showed Drake to have been a man of broad, far-reaching views, to whom his city and State owe much in many ways.

The next meeting of the Association is to be held at Newport, R. I., the first Tuesday in June, 1889. The last time the Association met in New England was in Boston, in 1865. The only drawback at Cincinnati was the warmth and closeness of the weather, and in this respect, at least, Newport should offer better conditions.

**A CONTRIBUTION TO THE STUDY OF GASTRO-
INTESTINAL ANTISEPSIS.**

In a paper read at the recent meeting of German physicians at Wiesbaden, Escherich discusses the different antiseptics in use at the present day, which he divides into three groups: soluble antiseptics (corrosive sublimate, phenic acid, boric, salicylic, benzoic, lactic acid, creasote, thymol, resorcin); antiseptics having little solubility (calomel, iodoform, naphthalin); insoluble antiseptics (salicylate of bismuth, salol, betol). While assigning to the medicines of the first group, if they are taken into the stomach in a sufficient state of concentration, a decided microbiocidal action, it is none the less true that by reason of their ready absorption from the stomach their disinfectant action on the intestine is almost nil. Hence, where intestinal antiseptics are really demanded, the insoluble agents should be chosen; of these, salicylate of bismuth is the type.

Escherich attributes to disinfectant lavages of the stomach a great value in gastric dyspepsia with stasis and fermentation of the food. After syphoning out the contents of the stomach, he performs a thorough lavage with a solution of resorcin, one-half per cent., or benzoate of sodium, three per cent.

In gastro-intestinal fermentations, great pains should be taken to ascertain the quality of the fermentation. In acid fermentation, Escherich forbids cow's milk and all sweet substances, substituting saccharine and glycerine for sugar; peptones, juice of meat and albuminous water for milk. In alkaloid fermentations, he counsels dextrine and the starches in preference to cane

sugar or grape sugar, which are almost wholly absorbed from the stomach. *Appropos* of the treatment of putrid decompositions of the intestinal canal by hydro-carbons, he recalls to mind the case of Moore, who caused disappearance of the putridity of the stools in an infant of sixteen months by the administration every two hours of teaspoonful doses of powdered sugar.

THE MONOPOLY OF ANTIPIRYNE.

THE French Board of Hospital Charities (Administration de l'Assistance publique) has decided to institute the manufacture of and supply the hospitals of Paris with antipyrine, which will henceforth be dispensed under the name *analgesine*.

This move will tend to break the monopoly in this valuable medicine, with whose chemical composition and methods of fabrication manufacturing pharmacists are sufficiently familiar.

The firm that has hitherto had the monopoly of the manufacture and supply of dimethoxyquinizine, because of the patent on the name *antipyrine*, has become immensely rich out of the large profits accruing from this monopoly. Attention has frequently been directed in these columns to that objectionable feature of antipyrine—that, although its chemical composition was known, it was a patent and proprietary drug.

MEDICAL NOTES.

—We learn from English exchanges that the heart disease from which Mr. Matthew Arnold died was hereditary in his family to a marked degree. Not only did the Mr. Arnold's grandfather and his father, the late master of Rugby, die from this cause, but he had also lost a brother from heart disease. A possible explanation of his rashness in jumping as he did, lies in the fact that when a student at Oxford he was nearly the champion at a high jump.

—Dr. T. E. Chatard, Jr., recently read before the Obstetrical Society of Baltimore, the statistics of his father's midwifery practice in Baltimore, between the years 1828 and 1883. The cases numbered 5,263, and were entirely in private practice and mostly in the well-to-do classes. He used no antiseptic precautions whatever, further than ordinary cleanliness, went from puerperal fever direct to other confinements, and attended labor cases while taking care of all sorts of infectious diseases. He had in all 26 cases of puerperal fever with eighteen deaths. During the last 18 years of his practice with 1,200 births, he had no case of the disease. The only period in which there seemed to be any epidemic was in 1845, when he had 10 cases, five in one month. Yet in this same month he attended eight other women who had no sign of the fever.

—The circular of the Marine Hospital Service, under date of April 26th, which happens by a curious coincidence to be about the close of the season of

Northern travel and sojourn in Florida, contains numerous despatches, dated as far back as February 10th, giving particulars of yellow fever in various parts of Florida, at Sanford, Tampa, Plant City, and elsewhere. A lady, wife of a physician, died of yellow fever at Tampa, January 20th, and it was reported as acute Bright's disease. At Plant City, 120 cases and 9 deaths have occurred since October 5th, and the "cleaning up" has not been sufficiently thorough to satisfy Dr. Murray, who was detailed to investigate the epidemic, and who says that the lines of railroad from Tampa to Jacksonville are at various points infested by fomites, which will at the proper time give a good deal of trouble. At Jacksonville, itself, a continued fever, "affecting the highest circle of society only," was prevalent in February and March, with a mortality of 6 to 8%, and presenting the characteristics, according to the attending physician, of enteric fever. But some other physicians have entertained the idea of its being yellow fever.

BOSTON.

—Dr. Durgin, Chairman of the Boston Board of Health, issued May 10th the following circular through the daily press. "The Board of Health estimates that there are not less than 100,000 persons in this city who, if exposed to smallpox, would probably contract the disease, and in view of the fact that several cases have lately been found in the city, the board earnestly advises all persons to apply at once to their family physician for vaccination, or at the city building on Chardon Street, where free vaccination is done from 9 to 11 A. M. No person should trust to a vaccination in childhood for protection through life." The suggestions of the circular are meeting with immediate response.

NEW YORK.

—The commencement exercises of the College of Physicians and Surgeons were held in one of the large lecture-rooms of the new College building on May 10th. The graduates numbered 120, and the address to the class was delivered by the President of the College, Dr. John C. Dalton. The first Harson prize of \$500, for the best examination in all branches, was awarded to Robert A. Sands, a son of Professor Henry B. Sands.

—At the last meeting of the New York Medico-Legal Society, held at the Hotel Buckingham, May 9th, the President, Mr. Clark Bell, announced that the preliminary Committee of Arrangements appointed at the April meeting to take the initial steps for an International Congress of Medical Jurisprudence in New York, had proposed the first Tuesday in June, 1889, as the date for the opening of the Congress. This recommendation having been approved by the Society, the Chair stated that a permanent Committee of Arrangements would be appointed at an early day.

—The commencement exercises of the Mount Sinai Hospital Training School for Nurses, were held May 10th, at the Home on Lexington Avenue, near the

Hospital. There were seven graduates, and prizes were awarded for excellence in ward duty and for the best essay on nursing.

— A meeting was held at Delmonico's on Thursday evening, May 10th, for the purpose of enlisting increased interest on the part of the public in the summer work of St. John's Guild. Among the speakers was President Bayles, of the Board of Health, who said that it was his experience and that of the Sanitary Inspectors, that nothing in the way of organized charity in New York, had done so much to protect infant life from the dangers which beset it in warm weather in the tenement-house districts, as the floating hospital and seaside nursery at New Dorp, Staten Island, maintained by the Guild.

Miscellany.

HEMI-CHOREA FOLLOWING PARTURITION.

A very interesting case was lately presented at Dr. Osler's clinic at the Philadelphia Orthopædic Hospital, as reported in the *Medical Times*. Mrs. X., the mother of three children, had an attack of inflammatory rheumatism four months after the birth of her last child. From this she recovered, but four months afterward chorea appeared, commencing in the right thumb, and the twitching extended up the entire arm, and subsequently appeared in the right leg, in which the motion was more marked than in the upper extremity. The choreic movements were confined to the right side. When she applied to the dispensary the above condition was noted; examination of the heart revealed a systolic basic murmur. No valvular lesion was detected. The movements were much worse in damp or stormy weather, so that at times she was not able to walk across her room. She was treated by Fowler's solution, five drops three times daily, and increased until doses of ten or twelve drops were taken, or half a drachm daily. An interesting point in the case consisted in the fact that the patient had never had chorea in childhood, and none of her family had been similarly affected.

DIRECT MEDICATION OF THE SPINAL CORD.

In the *New York Medical Journal* for October 31, 1885, and also in the *Boston Medical and Surgical Journal* for December 9, 1886, Dr. J. Leonard Corning, of New York, describes a method of influencing the functions of the cord by injecting medicinal substances of various kinds into its immediate vicinity. Since the publication of the above papers, he has introduced a variety of improvements in the technique of the procedure, which, he thinks, render it at once safe and practical. In the *Medical Record* for March 17, 1888, he gives a detailed description of the various steps involved in the operation. Having examined the vertebrae of the lower portion of the spinal column, Dr. Corning found that the posterior surface of the transverse process, even at its greatest depression, though almost on a level with the posterior aspect of the foramen vertebrae, did not fall at all, or, in rare cases, very slightly below it. Appropriating this

anatomical coincidence, he has formulated a mode of procedure described in the article referred to above.

This is certainly a radical departure in the therapeutics of the cord, and one, too, which cannot fail to attract the attention of the practitioner.

ALBUMINURIA FROM SEWAGE-POISONING.

DR. GEORGE JOHNSON (*British Medical Journal*, March 3, 1888, and *Practitioner*, April, 1888) directs attention to the fact that amongst the many causes of blood-contamination and consequent albuminuria, sewage-poisoning is a by no means an infrequent one. In addition to other forms of disease the result of drain-poisoning, he has met with a number of cases of *albuminuria* which have been clearly traceable to this cause. Just as the occurrence of a case of typhoid or diphtheria in a house would, as a matter of course, excite attention to the drainage and the water and milk supply, so, in the absence of other probable exciting causes of albuminuria, the possibility of sewer-poisoning should be constantly borne in mind. He describes the following as a typical instance of this connection: A gentleman of forty had been ailing on and off for some four or five months, but had been worse during the last month. There had been soreness of the throat and neck, occasional rigors, and a temperature of 102°. A week before the urine had been tested, and found highly albuminous; it was now scanty, turbid with urates, specific gravity 1030. It contained seven grammes per litre of albumen, and when it was cleared by warmth, small hyaline, epithelial, and leucocyte casts were seen. The pulse was full and throbbing. No oedema. The patient was of temperate habits; he had not been exposed to cold; and, in the absence of other apparent exciting cause, Dr. Johnson expressed his conviction that drain-poisoning had been the cause of the sore throat, occasional rigors, and albuminuria. On inquiry, it was found that sewer-gases had been escaping into his house from two untrapped waste-pipes, the one connected with a washing basin in a lavatory, the other with a bath, and both going direct into the drain. The patient remained at the house of a relative until he recovered. He was treated in the usual way by rest in bed, milk diet, warm baths, and purgatives. In about a week the albumen began to decrease; in three weeks it had entirely disappeared, and it has not recurred, the urine being quite normal. It is highly probable that if the cause of this man's illness had not been discovered and removed, continued exposure to the sewer poison would have resulted in an incurable disorganization of the kidneys, as has happened in several cases that have come under Dr. Johnson's observation.

THE TREATMENTS OF COLDS AND BRONCHITIS.

THE variations which have taken place in the treatment of this important class of affections, and the most approved treatment of the present time, are referred to in an interesting editorial in the April number of the *Therapeutic Gazette*, from which we make the following extracts:

When the cold is a widespread, general one, involv-

ing the whole body in a condition which, according to our own thinking, is a form of subacute rheumatism, with aching pains and general wretchedness, a free laborant sweat, followed by a few full doses of quinine, will often liberate the sufferer at once, especially if the sweats be aided by a mercurial or other purgation. Coryza has long been a bugbear to the family doctor, but, thanks to bismuth and cocaine, we are now enabled to view it without tremor. We learnt also quite recently a curious lesson from an old barber: Happening to be in the shop when suffering from a violent cold in the head, the grizzled remnant of a colored regiment, now Junior Vice-Commander (Brigadier-General) of the Grand Army of the Republic, offered at once to cure us by manipulation. After much banter and the agreement of no cure, no pay, the editorial head was well manipulated by the mysterious procedure known as dry shampooing, and the result certainly was that the coryza disappeared. Bismuth and cocaine injections into the nose, we think, almost invariably, however, bring relief without calling in the assistance of the manipulator.

A mixture which we have often used with great advantage, and which is readily prepared in the household without the intervention of the apothecary, is made by adding a dessertspoonful each of whiskey, paregoric, and glycerin, and thirty minims of chloroform; the whole to be well shaken, and to be taken in teaspoonful doses *pro re nata*. In our earliest medical teaching was inculcated a profound faith in the value of hydrocyanic acid and wild cherry bark as a means of quieting a cough. Wild cherry bark preparations contain scarcely more than a trace of the prussic acid, and certainly are useless.

The ordinary depressing expectorants of our boyhood and of the text-books have in our practice been replaced very largely by the citrate of potassium. If tartar emetic or ipecacuanha be given in such dose as to produce prolonged nausea and vomiting, it will undoubtedly usually bring about free secretion in the early stages of acute bronchitis, but the method is so disagreeable and so exhausting that it is only to be tolerated when the patient is a robust man, to whom time is so important that it is essential that he be cured in the most speedy manner possible, even at great bodily inconvenience and some risk. Unless the older depressant expectorants be given in nauseating doses they have comparatively little power, and we think that any of our readers who will use the following cough-mixture in the first stages of bronchitis will never depart from its employment, unless some new remedy of greater power be discovered. The dose of it, of course, must be varied according to the strength and peculiarities of the individual patient. That which we indicate is for a robust man:

R. Potass. citrat.,	3 i.
Syr. limonis,	f 3 iss.
Syr. ipecac.	f 3 ss.
Tr. opil. camphor.	f 3 ii.
Syrup. q.s. ad	f 3 iii.
S. Dessertspoonful every two hours.		

Of the older stimulating expectorants, the only ones which still retain our confidence are the muriate of ammonium and the syrup of garlic. The ammonia salt does seem to have a very peculiar influence upon the respiratory mucous membrane. It is valuable in acute bronchitis when free secretion has once been established, but in some cases it seems also to have the power of bringing about secretion. In the

rare instances in which the citrate of potassium mixture fails, we habitually resort to the muriate of ammonium, and have often seen very good results.

RESOLUTIONS OF WORCESTER DISTRICT MEDICAL SOCIETY ON THE LATE DR. R. K. CLARKE.

Whereas, The Worcester District Medical Society has received with sincere sorrow the intelligence of the decease of our late respected friend and associate, Dr. R. K. Clarke:

Resolved, That by the death of Dr. Clarke, this Society has lost one of its most worthy members, a man of most excellent judgment and skill in his profession, and always interested in all movements looking towards its advancement.

Resolved, That the community among whom he walked, has been deprived of a physician who fulfilled in a rare degree all the duties and obligations belonging to that profession, and one who endeavored throughout his forty years of active practice among them to be a true representative of the noblest and highest principles governing the medical profession.

Resolved, That in our sorrow we appreciate the fact that one of our profession and a member of our Society should have been so prominent in, and should have served so faithfully his country, his state, his district, and his town; and that through him we have contributed so largely, not only to that which pertains to the physical welfare of Society, but also to its educational and moral interests.

Resolved, That the proceedings of the Worcester District Medical Society this day in honor of our late lamented brother, be engrossed upon the records and communicated to the family of the deceased, with the assurance of our deep sympathy in their bereavement; also that a copy be transmitted to the *Boston Medical and Surgical Journal* for publication.

(Signed)

W. H. LINCOLN.
O. H. EVERETT.
LEONARD WHEELER.

WILLIAM B. GOLDSMITH, M.D.

At the meeting of the Boston Medico-Psychological Society held April 19th, special reference was made to the recent death of Dr. W. B. Goldsmith, and a committee was appointed to prepare resolutions, to be reported to the Society at a subsequent meeting.

This Committee reported as follows:—

"The Boston Medico-Psychological Society, deeply impressed with the loss it has sustained by the death of its beloved member, Dr. William B. Goldsmith, Superintendent of the Butler Hospital, at Providence, R. I., wishes to place on record its testimony to his exalted character, his great ability as a physician and a superintendent, and his genial and generous nature as an associate.

Dying at the early age of thirty-four, when it seemed that a long life of usefulness had only just begun, he had already accomplished, by his great attainments and faithful, conscientious work, that of which older men might well be proud; and had made his influence felt, not only in the hospitals, but also in the community, in wider knowledge of mental disease, and more intelligent and liberal treatment of the insane.

Resolved, That by his death this Society has lost one of its most distinguished members, a valued contributor, and each of us a tried and cordial friend.

Resolved, That the Secretary of the Society, in communicating to the family of Dr. Goldsmith this expression of its esteem, and its sorrow at his death, be requested to extend to them our heartfelt sympathy in their grief.

GEORGE F. JELLY,

PHILIP COOMES KNAPP, } Committee.

Correspondence.

DIABETIC FOOD.

BOSTON, May 12, 1888.

MR. EDITOR,—The readers of the JOURNAL will remember the well-timed article by Dr. Chas. Harrington, showing the utter worthlessness of so-called diabetic breads and flours, and giving the results of his analysis of the same, also the able discussion which followed.

Neither this exposure nor the fear of Chap. 208, Sec. 3, Public Statutes, which says: "Whoever fraudulently adulterates for the purpose of sale bread or any substitute intended for food with any substance injurious to health shall be punished by imprisonment, or fined not exceeding

¹ Journal, Vol. cxvii, No. 12, pp. 286 and 291.

three hundred dollars, and the article so adulterated shall be forfeited and destroyed under the direction of the court," seem to deter these parties from continuing their fraudulent practices of foisting upon the public diabetic breads and flours, which are so in name only.

It appears that Dr. Pavy² found even a worse state of affairs in relation to diabetic foods than did Dr. Harrington, for while the analysis of the latter gentleman shows the several foods in question to contain as follows: 30 per cent. starch = 35 per cent. sugar; 36 per cent. starch = 40 per cent. sugar; 40 per cent. starch = 44 per cent. sugar; 66.96 per cent. starch = 74.40 per cent. sugar; those analysed by Dr. Pavy are said by him to yield as high as 84 per cent. and 89 per cent. starch.

It will be conceded on all sides that the chief obstacle in the treatment of diabetes when the diet must be restricted

is the difficulty of obtaining a proper substitute for bread, or in other words, a food practically minus starch. The above facts, therefore, taken in connection with the increase of diabetes, has prompted the writer to give some thought to the preparation of a diabetic bread and flour, and the result demonstrates that a palatable, nutritious and inexpensive bread can be made from the following; viz. chemically pure gluten flour, lignose and cellulose from potato, etc., etc. Bread prepared from this formula gives, at the hands of Dr. B. F. Davenport, dextrose, 17 per cent.; anhydrous starch, 15.28 per cent. = 16 per cent. sugar.

The reader will kindly compare with the analysis above quoted. In conclusion, I would state that the American Health Supply Company, of Boston, has agreed to supply physicians and their patients with preparations from this formula.

Very truly yours,

A. GASTON ROETH, M.D.

Deaths reported 2,224: under five years of age 760; principal infectious diseases (small-pox, measles, diphtheria and croup) 374; diarrhæal diseases, whooping-cough, erysipelas and fevers) 374; acute lung diseases 447; consumption 325; diphtheria and croup 122; diarrhæal diseases 66; scarlet fever 41; typhoid fever 34; measles 32; cerebro-spinal meningitis 19; whooping-cough 17; erysipelas 12, malarial fever 9, puerperal fever 7. From typhoid fever, Philadelphia 16, New York six, Baltimore, Washington, Pittsburgh and Milwaukee two each, Lowell, Fall River, Lawrence and Gloucester one each. From measles, Washington 11, Baltimore seven, New York and Milwaukee five each, Pittsburgh three, Holyoke one. From cerebro-spinal meningitis, New York nine, Philadelphia three, Worcester two, Baltimore, Boston, Milwaukee, Lynn and Salem one each. From whooping-cough, New York seven, Philadelphia four, Baltimore and Charleston two each, Boston and Washington one each. From small-pox, Philadelphia seven, New York six. From erysipelas, New York five, Philadelphia, Boston and Mil-

waukee two each, Pittsburgh, Worcester and Lynn one each. From malarial fever, New York eight, Philadelphia one. From puerperal fever, Philadelphia and Milwaukee two each, Boston, Pittsburgh and Lawrence one each.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending April 21st, the death-rate was 19.9. Deaths reported 3,585: infants under one year of age 813; acute diseases of the respiratory organs 363; whooping-cough 151; scarlet fever 48; diarrhæa 44; fevers 40; measles 37; diphtheria 25; small-pox (Sheffield 12, Hull three, Oldham two, Bristol and Manchester one each) 19.

The death-rates ranged from 29.6 in Plymouth to 15.7 in Brighton; Birmingham 21.3; Bolton 19.8; Bradford 17.9; Hull 17.0; Leeds 22.4; Leicester 17.8; Liverpool 19.7; London 18.9; Manchester 13.9; Nottingham 18.8; Sheffield 21.1; Sunderland 16.2.

In Edinburgh 20.1; Glasgow 22.6; Dublin 24.8.

The meteorological record for the week ending May 5, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending Saturday, May 5, 1888.	Barom- eter.	Thermometer.		Relative Humidity.		Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 5, 1888, TO MAY 11, 1888.

McKEE, JAMES C., lieutenant colonel and surgeon. Granted leave of absence for one month. S. O. 107, A. G. O., May 9, 1888.

GREENLEAF, CHAS. R., major and surgeon.

O'REILLY, ROBERT M., major and surgeon.

SKINNELL, JNO. O., captain and assistant surgeon. Detailed as members of a Board of medical officers to assemble at the United States Military Academy, West Point, N. Y., on June 1, 1888, to examine into the physical qualifications of members of the graduating class and of the candidates for admission to the Academy. S. O. 101, A. G. O., May 5, 1888.

BROWN, HARRY E., major and surgeon. The leave of absence for seven days granted by Order No. 68, Fort Barrancas, Fla., May 2, 1888, is extended twelve days. S. O. 90, Division of the Atlantic, May 8, 1888.

LORING, LEONARD Y., captain and assistant surgeon. Granted leave of absence for three months on surgeon's certificate of disability. S. O. 106, A. G. O., May 7, 1888.

BROWN, PAUL E., captain and assistant surgeon. Granted leave of absence for six months on surgeon's certificate of disability, with permission to leave the Division of the Atlantic. S. O. 107, A. G. O., May 9, 1888.

BENHAM, ROBERT B., captain and assistant surgeon. To proceed from Fort Du Chesne, to Fort Douglas, Utah, and report to commanding officer of that post, not later than 25th inst., to accompany battalion of Sixth Infantry to Fort Lewis, Colo. Upon completion of this duty, will return to his station, Fort Du Chesne, Utah. S. O. 35, Department of the Platte, May 3, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 12, 1888.

CABELL, A. G., passed assistant surgeon. Detached from "Adams," proceed home and wait orders.

SIMONS, M. H., surgeon. Detached from Naval Academy and to practice ship "Constellation."

ROKOWITZ, P. J., medical director. Leave of absence for six months to leave the United States.

A Naval Medical Examining Board is now in session at the Naval Hospital, Philadelphia, for the examination of candidates for admission to the Medical Corps of the Navy. There are eleven vacancies in the list of Assistant Surgeons. Permits for examination can be obtained on application to the Secretary of the Navy.

SOCIETY NOTICE.

MASSACHUSETTS MEDICAL SOCIETY.—One Hundred and Seventh Anniversary. The Annual Meeting will be held at 9 o'clock, A. M., Wednesday, June 13, 1888, in Huntington Hall, at the Institute of Technology, Baylston Street (between Berkeley and Clarendon), Boston. Twelve o'clock, M., the Annual Discourse, by B. Jay Jeffries, M.D., of Boston. One o'clock, P. M., the Anniversary Chairman and Invited Guests will meet the Fellows of the Society at a Reception and Banquet to be held at Hotel Vendome. The Fellows, in order of seniority, will walk in procession to the entrance on Commonwealth Ave-

nue. To enable the Committee to make suitable arrangements, it is earnestly requested that Fellows procure tickets before noon on Wednesday. The usual arrangements have been made for the preceding day, Tuesday, June 12th. By order of the President. FRANCIS W. GOSS, Recording Secretary.

Roxbury, May 14, 1888.

PRELIMINARY ANNOUNCEMENT OF THE COMMITTEE OF ARRANGEMENTS OF THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.

This Association will hold its first triennial session in the city of Washington, during the 18th, 19th and 20th of September next. The meetings of the Congress will be held in the evenings, beginning at 8 P. M., and those of the Societies composing the Congress will be held during the day-time, according to the programme each may respectively provide. The sessions will be open to the profession.

The Local Committee of Arrangements of the Congress has secured places of meeting for the Congress and each Society in close proximity, so that the members of the respective societies can interchange attendance at pleasure, without inconvenience.

It is the purpose of the Executive Committee of the Congress to make provision for the programmes of all of the societies, provided copies be supplied on or before August 15.

The Local Committee requests the secretaries of the societies to forward the names of those of their invited guests who have accepted their invitation, designating them as Foreign and American.

The Committee of Arrangements is composed of one member of each society represented in the Congress, as follows:

SAM'L C. HURSE, Association of Am. Physicians, Washington.
J. FORT THOMPSON, Am. Surgical Association, Washington.
R. T. EYES, Am. Neurological Association, Washington.
E. C. MORGAN, Am. Laryngological Association, Washington.
W. W. JOHNSON, Am. Climatological Association, Washington.
J. E. FRANKLIN, Am. Dermatological Association, Baltimore.
A. SYDNEY ROBERTS, Am. Orthopedic Association, Philadelphia.
H. NEWELL MARLIN, Am. Physiological Society, Baltimore.
SAMUEL THEODOR, Am. Ophthalmological Society, Baltimore.
S. C. HENCK, Am. Otolaryngological Society, Washington.
A. T. CAROT, Am. Association of Genito-Urinary Surgeons, Boston.

Inquiries may be addressed to the Chairman, Dr. Bussey, at Washington, or to the representative member of each Society on the Committee.

It may also be stated that the Committee of Arrangements of the American Gynecological Society, which will hold its next annual meeting in Washington at the same time, is composed of Drs. Bussey, Taber, Johnson, and King.

BOOKS AND PAMPHLETS RECEIVED.

Reports of the Home for Sick Children, Cincinnati. October 1, 1883, to October 1, 1887.

Original Articles.

THE ORIGIN OF TYPHOID FEVER IN HOSPITALS, AND THE MEANS SUGGESTED FOR ITS PREVENTION. A CONTRIBUTION.¹

BY REGINALD H. FITZ, M.D.,
Visiting Physician to the Massachusetts General Hospital.

IN his article on "Typhoid Fever" in Pepper's "System of Medicine" (1885, I, 248), Dr. James H. Hutchinson says: "During the past twenty-four years I have been almost uninterruptedly connected with large general hospitals, and during that time have had a large number of cases of typhoid fever under my care, and a still larger number more or less under my observation. During all this time I have never known but one case to originate within a hospital, and that occurred in a servant whose duties did not bring her in immediate contact with the sick."

During my service in the wards of the Massachusetts General Hospital in the summer of 1887, there was admitted a young girl, suffering from debility and hysterical paraplegia. After a stay of four weeks, in which time she had greatly improved, she was transferred to the Convalescent Home in Belmont. On the day following her arrival, symptoms of typhoid fever made their appearance. Three days later she returned to the Hospital, and remained there till her recovery from the attack. The suggestion was so direct that her disease owed its origin to causes existing within the Hospital, that it seemed desirable to make an inquiry into the frequency of such cases, with the view of preventing their occurrence. The visiting physicians appointed Dr. Tarbell and the writer a committee for the above purposes, and the present communication is the outcome of their research.

It is obvious that the discovery of a small number of isolated cases, extending over a given period of years, is of as much importance in demanding a remedy as the occurrence of many cases in the same length of time or in a shorter period. Some of the visiting physicians were able to recall solitary instances, and letters were written to the several gentlemen who had served as medical house-officers during the past ten years. From their intimate relations to the patients, it was thought they would be most likely to remember the class of cases under consideration. Ward-tenders, nurses, and other employés were also asked to assist in the search.

The names of a number of patients were thus secured, and the records of the Hospital were examined for the detailed description of their symptoms. The following abstracts were made from these records:

CASE I. October 24, 1882, medical externe. In charge of the Convalescent Home, but came each day to the Hospital, where he stayed some six hours. Has not felt perfectly well for a week, but his disease began five days before he entered the Hospital as a patient. The symptoms were those of typhoid fever; he died on the eleventh day, and the characteristic lesions were present.

The home at Belmont is designed solely for convalescents, especially for those able to take care of themselves. It contained no cases of typhoid fever. On the contrary, numerous patients with this disease are to be found during the autumn in the Hospital. Although the evidence is insufficient to warrant the as-

sumption that this case arose from causes existing within the Hospital, the possibility of such an origin is obvious.

CASE II. September 11, 1883, medical nurse. She has been a hospital nurse in Lynn for several months, but has been employed at the Massachusetts General Hospital for the past nineteen days. Has felt tired for some time, and for the past two weeks has had nausea and dizziness in the morning. Four days ago was attacked with chills, headache, and pain in the bowels. There is now some tenderness on pressure at the right of the abdomen. The temperature rose gradually during the first week to 105° F., then descended, day by day, for nine days, till it reached the normal point. It remained in the vicinity of 99° F. for several days, and she was discharged well nearly two months after her admission as a patient.

The evidence afforded by this case is rather one of possibility than of probability. If she had become infected with the typhoid poison before her presence in the Hospital as nurse, a period of fifteen days elapsed before suggestive symptoms were apparent. It is evident that with such a period of incubation, the disease may have been contracted before she became employed at the Hospital. On the other hand, an interval of fifteen days is quite sufficient to permit the infection to have occurred from conditions existing within the Hospital, in which case her debilitated state may have acted as a favoring cause.

CASE III. October 26, 1883, medical and surgical nurse. She has been on duty in the Hospital for seven months. During the past three weeks has felt very tired at night, and has suffered from occasional headache. These symptoms have been much worse during the past three days. Two sharp chills to-day, and intense pain in the head. Temperature 103° F. The temperature rose to 105° F. during the first three days, and gradually fell to the normal, being 101° F. at the end of the third week. She was discharged well, 13th of December. The conspicuous symptoms of her attack were headache, nocturnal delirium, and prostration. An eruption resembling rose-spots and sudamina were observed.

The above is regarded as a case of probable intra-hospital origin. It is, of course, possible that the morbid poison may have been obtained from sources without the Hospital. The presence of typhoid patients, and the constant exposure of the nurse to the influences emanating from them, offer a more direct explanation of the origin of the attack.

CASE IV. November 20, 1884, medical ward-tender. For two weeks he has had malaise, with increasing anorexia. Headache for several days. Diarrhea and chills in the past two days. Temperature 102° F. From this point the temperature rapidly rose to the maximum, 105° F., and gradually fell to normal, which it reached in the fifth week. Recovery then took place. Rose-spots and gurgling in the right iliac fossa are recorded; also diarrhoea, sordes, delirium, and twitching of tendons of wrist.

This patient is reported to have been not over-cleanly in his habits. He is said to have eaten his meals without any preliminary hand-washing, immediately after giving the bed-pan to a typhoid patient. In the light of his habits and exposure, it seems fair to regard this case as having originated within the Hospital.

CASE V. August 10, 1885, medical and surgical

¹ Read before the Boston Society for Medical Improvement, April 23, 1888.

ward-servant. For the past eight days she has had headache, loss of appetite, epigastric pain and malaise. Five days ago she went into the country but has felt hot and weak. There have been free movements of the bowels during the past three days. She returns to the hospital for treatment with tenderness and gurgling in the right hypogastrium. Temperature 102.4° F. At the end of twelve days the temperature became normal and recovery then took place. Doubtful rose-spots were noted.

The ward in which this person was employed is filled with private rooms, in one of which was a typhoid patient at the time she was taken sick. There seems no reason to suppose that she was infected during her brief absence from the Hospital. She left on account of illness, and was away too short a time for typhoid fever to have been acquired, except in the most violent cases.

CASE VI. November 15, 1886, medical interne. Restless five days ago, since when has had headache, backache and malaise. Death occurred at the end of the third week. The symptoms observed during life and the lesions found after death were characteristic of typhoid fever.

CASE VII. May 24, 1887, medical nurse. She has had several cases of typhoid fever under her care during the past month. In this time she has suffered from headache, general malaise and gradual loss of appetite. Three days ago the headache became very intense; there was severe backache and general weakness. Took her bed yesterday; temperature 103.4° F. Tenderness and gurgling are now present in the right iliac fossa. Rose-spots subsequently made their appearance. The temperature became normal at the end of the fourth week and she recovered.

The last two cases require no comment as the probability is direct that their origin was due to exposure in the hospital.

CASE VIII. June 20, 1887, medical patient. She entered May 18th, suffering from debility, and was sent to the Convalescent Home, June 1st. She remained there ten days, and, when discharged, never felt so well in her life. Three days later she went to a hotel as chambermaid, but after three days' service lost her appetite, was dizzy and chilly. On the following day she had persistent vomiting and the onset of a diarrhoea, which has since continued. There is now tenderness and gurgling in the right iliac fossa. Temperature 104.4° F. Rose-spots subsequently appeared. The temperature reached 105° F., on the second day in the Hospital, and fell to 99° F. at the end of the fifth week. She was discharged well.

It seems probable that the origin of the disease in this case is to be sought rather in influences existing in the hospital than in those at the Convalescent Home, or in the hotel. A period of incubation of at least sixteen days is necessary to support the first assumption. The experience of the hospital in connection with the cases of typhoid fever received from the steamship *Prussian*, shows that infection within this limit is quite possible. This ship landed her passengers in Boston May 10, 1887, having been ten or twelve days on her voyage from Glasgow. Two days later cases of typhoid fever arose among her passengers and eventually, as I am informed by Dr. S. H. Durgin, of the Board of Health, about one-sixth suffered from the disease. Many of the patients were admitted to the hospital. In two of these the symp-

toms did not appear until the 24th and 25th of May respectively. It is, of course, impossible to say at what time the infection of these cases took place. But as an interval of fifteen days occurred between the arrival of the ship and the outbreak of the disease in one case, a period of incubation of sixteen days is evidently quite possible.

The infection of Case VIII is also more likely to have taken place at the Hospital than at the Home, because the latter contains no acute cases. It is least likely to have taken place in the hotel on account of the then necessarily brief period of incubation. The case is classified, however, as one of possible, not of probable, origin in the hospital.

CASE IX. September 18, 1887, medical patient. She entered the Hospital a month ago with hysterical paraplegia, improved rapidly, and was sent to the Convalescent Home September 6th. On the day after arrival she had headache and dizziness, soon followed by diarrhoea, and on the following day she was obliged to take to her bed. She is re-admitted to the hospital with a temperature of 104.2° F., tenderness on pressure in both iliac regions, rose-spots and enlarged spleen. The temperature was at its maximum on the sixth day and remained at the normal point from the twelfth to the nineteenth day. A relapse then took place lasting some five days. She was discharged well. There seems no room for doubt that this case owed its origin to causes existing within the Hospital.

CASE X. September 19, 1887, medical patient. This woman entered without any history of previous illness, on the fifth day of an apparent attack of acute articular rheumatism. A systolic souffle was heard at the apex on the fifth day after admission, and two days later a friction-sound was recognized at the base of the heart. The temperature was 101.8° F. It remained between 100° F., and 101° F., till the sixteenth day when it rose for four days, reached its maximum 104.4° F., then gradually fell to the normal. Defervescence extended over a period of nearly six weeks. Two days after the rise began the abdomen is found to be "full and tympanitic, slightly tender in the right iliac region. Tongue dry, with thick brownish coat, sordes on teeth, mental condition dull. A few hyperemic papules, redness disappearing on pressure, are present." On the next day "the wrists are tender on pressure," and several movements of the bowels occurred during forty-eight hours. Two days later a systolic souffle is distinctly heard in the pulmonic area and the pulmonic second sound is accentuated.

"The abdomen is covered and the posterior aspect sprinkled with nearly circular spots varying in size from a large pin's head to size of a cent, with intervening healthy skin. These patches are raised above the surface, the larger ones more so at the periphery than at centre. Smaller ones pretty uniformly raised. They have dull red margins, redness disappearing on pressure. 'Annular Roseola.'"

Twelve days later, the general condition of the patient progressing satisfactorily, it is noted, "wrists somewhat painful on motion. An indistinct souffle can be heard over base of heart."

During the rest of her stay in the Hospital, the slight pain and tenderness in the joints persisted for some time. The souffle near the pulmonic area disappeared, but marked pulmonic accentuation persisted.

Although this case is registered as one of typhoid

fever, the possibility of its being one of rheumatism is admitted. Many of its characteristics will be recognized as those occurring in acute ulcerative endocarditis. If the case be regarded as one eventually of typhoid fever, it is obvious that the latter disease may have originated, as a complication, from causes within the Hospital. A period of eleven days had elapsed after her admission before the existence of possible typhoid fever seemed probable. The case is, therefore, included as an illustration of possible typhoid of intra-hospital origin, although this possibility is regarded as doubly remote.

CASE XI. November 28, 1887, medical ward-tender. Well till three days of failing appetite; pain in the back and limbs and cough were followed by pain and tenderness in the right inguinal region, and fever. There was splenic enlargement, crops of doubtful rose-spots, and a continued fever, lasting four to five weeks. Recovery then took place.

The following table summarizes the results of this inquiry: Eleven cases of typhoid fever, of which seven probably and four possibly originated in the Hospital.

		Medical Officers.	Ward- Tenders.	Nurses.	Ward- Servants.	Patients.
1882	Probable Possible	1
1883	Probable Possible	1 1
1884	Probable Possible	..	1
1885	Probable Possible	1	..
1886	Probable Possible	1
1887	Probable Possible	..	1 ..	1	1 2
Total		2	2	3	1	3

The degree of probability that these seven cases were infected in the Hospital may present itself differently to each of a number of interested persons. It is impossible that the evidence obtainable in such cases can have more than a relative value.

It being admitted that the diagnosis is correct, the data which must lead towards conviction are based on the known variations in the period of incubation, the presence of typhoid cases in the wards, the occurrence of isolated cases during a period of years, and their exclusive limitation to persons connected with the medical or mixed medical and surgical wards.

In Hutchinson's paper, already referred to (p. 260), the following statement is the result of a consideration of the length of the period of incubation: "The conclusion would seem to be justifiable that the period of incubation in typhoid fever is usually between two and three weeks, but that in many cases it does not exceed ten days, and in rare instances has unquestionably been very much less. On the other hand, there are authentic cases on record in which it is said to have reached, or even exceeded, twenty-eight days."

Of the eleven cases considered in this paper, seven were constantly associated with typhoid patients for months. The remaining four were exposed during periods varying from eleven days to one month. It is thus apparent that all the above cases may have been infected within the Hospital.

If the causes of infection were introduced from without, as by impure water or milk, or by contaminated articles of food, an epidemic of the disease would be expected, not isolated cases. Neither would they at all times be limited to the medical service of the Hospital. The same argument holds here with reference to the possible origin of the disease from leaky drains and sewers. The origin of the poison is, then, to be sought for in those typhoid patients who are regularly brought to the Hospital from Boston and the surrounding country.

The most prolific, if not the sole source of typhoid fever is to be found in the patient himself. His dejections are almost absolutely proven to contain the poison of the disease, and it is possible that secretions from the air-passages may also be infectious. The most thorough-going preventive measures are those which shall destroy the influence of both these agents. The more we regard typhoid fever as contagious in the sense of small-pox and scarlet fever, the more efficient will be our preventive measures. Dried feces and dried sputum are readily diffused by drafts of air. They are as readily inhaled or swallowed as the emanations from the most contagious of diseases. Prevention is best accomplished by destroying the emanations and burying the remains.

Such views are in no way novel, and, of late years, have been preached and practised more or less generally and with more or less vigor. I am indebted to Dr. H. B. Jacobs, medical house-officer, for the following account of the prophylactic measures used in a female ward of the Massachusetts General Hospital during the year 1887. They relate especially to the disposal of the dejections of typhoid patients. An empty, dry bed-pan is taken to the patient, and, after use, is covered and carried out of the ward to the hopper, where it is emptied. It is then rinsed with corrosive sublimate (1-1000) or with carbolic acid (1-20), and subsequently rinsed with water and dried with a cloth which hangs near the hopper. The latter is rinsed with the corrosive or carbolic solution, and water is allowed to run freely for several minutes. The hopper is scoured every morning with soap and sand. The cloth used in drying the bed-pan is changed every few hours; when wet or soiled, it is taken to the rinse-house with the soiled clothes. The patient is wiped with toilet-paper after the use of the bed-pan, and if unusually soiled, is washed with soap and water. If the dejections are involuntary, the patient is immediately washed, and the bed-clothes are changed. The soiled linen, including the gauze used in washing the patient, is carried to the rinse-house as soon as possible. If the bed-linen is particularly soiled it is sprinkled with a disinfectant before its removal.

Notwithstanding these precautions, which were carried out by intelligent, neat and conscientious nurses, two cases of typhoid fever apparently originated in this ward during the summer of 1887. Either the precautions were insufficient or the cases originated outside the hospital. The former alternative alone is under the control of the hospital authorities.

The requirements of disinfection consist in the ab-

solite cleanliness of the patient and his surroundings. This is accomplished by fresh air, daily baths, frequent changes of bed and body linen, the immediate changing of soiled clothes, and the rapid removal and destruction of all infective matter.

Until the researches instituted by Robert Koch,³ concerning the relative value of disinfectants, our knowledge of the subject was very inexact. Disinfectants and deodorizers were essentially one and the deodorizer was usually the one. It was found that sulphur fumes are not to be relied upon to destroy anthrax-spores, the well-known cause for a sharply defined infective disease, namely, malignant pustule. It is, therefore, obvious that they should not be depended upon to destroy the unknown germs supposed to produce other diseases of the same group.

Bromine and chlorine are capable of destroying anthrax-spores with which they are in sufficiently prolonged contact and in sufficient concentration. But their specific gravity is such that as ordinarily used, they cannot reach all parts of the rooms which they are supposed to disinfect.

Even now the recommendations, and, perhaps, requirements, of our boards of health, contain directions which have little in their favor even if they are not worse than useless. In Berlin, according to Pistor⁴ it was not till 1881 that any essential change was made in methods of public disinfection from those prescribed in 1835. In 1886 a further revision was made.

According to these regulations the use of bromine and chlorine is discontinued on account of the previously stated objections. Sulphur fumigations are not recognized as a trustworthy disinfectant, even when the conditions for their use appear to be most favorable. Corrosive sublimate is not employed in consequence of its poisonous qualities, and because it forms insoluble compounds with sulphuretted hydrogen, ammonia and albumen. In the disinfection of the city of Boston, in 1887, according to the sixteenth annual report of the Board of Health, there were used 16,592 pounds of sulphur in fumigation and 2,250 pounds of corrosive sublimate in solution.

The following suggestions for the prevention of the origin of typhoid fever in hospitals are based upon these revised Police-Regulations for Disinfection in Contagious Diseases. They are presented in the form of special directions to nurses in cases of typhoid fever. They have been examined by Dr. Pratt, the superintendent of the hospital, and have been amended and approved by him. They apply equally well to cases in private practice, and may be employed in all contagious diseases. The knowledge and experience of the physician will lead him to make such deviations from these rules as the individual case seems to demand or permit.

SPECIAL DIRECTIONS IN TYPHOID FEVER.

1. Mattresses and pillows (when liable to become soiled) are to be protected by close fitting rubber covers.
2. Bed and body linen are to be changed daily. Bedspreads, blankets, rubber sheets and rubber covers are to be changed at once, when soiled by the patient. Avoid shaking any of these articles.
3. All changed linen, bath-towels, rubber sheets and covers are to be immediately wrapped in a sheet soaked in carbolic acid (1-40). Remove to the rinse-house as soon as possible, and soak six hours in carbolic acid (1-40). Then boil the linen for a half-hour, and wash with soft soap. The rubber sheets and

covers are to be rinsed in cold water, dried, and aired for eight hours. The bedspreads and blankets are to be aired eight hours daily.

4. Feeding utensils are to be thoroughly cleansed in boiling water immediately after being used.

5. Dejections are to be received in a bed-pan containing half a pint of carbolic acid (1-20). The nates are to be cleansed with paper, and finally with compress cloth wet in carbolic acid (1-40).

6. The bed-pan and cloths are to be carried to the tower. Add two quarts of carbolic acid (1-20) in divided portions to the contents of the bed-pan, mix thoroughly by shaking, and throw the liquid into the hopper. The bed-pan and hopper are to be cleansed with carbolic acid (1-20), and wiped dry. The compress-cloths used for the above purposes are to be burned at once.

7. The corpse is to be covered with a sheet wet with carbolic acid (1-40), and removed to the Allen Street House.

8. After the discharge of the patient, mattresses are to be thoroughly beaten and aired every day for a week. The bedstead is to be washed with corrosive sublimate (1-1000).

9. These directions are to be followed until the patient is free from fever.

PROPER AND IMPROPER METHODS OF DISINFECTION.¹

BY CHARLES HARRINGTON, M.D.,
Instructor in Hygiene and Assistant in Chemistry in the Harvard Medical School.

For the proper practice of disinfection it is first of all necessary to discriminate between true disinfectants and antiseptics, the former of which destroy the vitality of micro-organisms, while the latter merely prevent or retard their development. This distinction is unfortunately not always borne in mind, and many processes of supposed disinfection are for this reason utterly valueless.

It is also of the very greatest importance that of the many agents recommended as true disinfectants none should be employed except those which have been thoroughly tried and proven by the most reliable and scientific methods, and any agent which fails to pass the requirements based on modern scientific research, should, without regard to its popularity, ease of application, cheapness, or long record of supposed efficacy, be abandoned.

Previous to the investigations of Koch and others of the Imperial Board of Health of Germany, the processes used in disinfection were very numerous, and, owing to a lack of definite knowledge of the subject, were applied in a hap-hazard manner. The list of supposed disinfectants was very long, and included many compounds which owed their supposed value to penetrating odors. The most valuable agent for the disinfection of rooms and furniture, ships and cargoes, was for many years considered to be the fumes of burning sulphur, the efficacy of which was demonstrated as early as 1771, though they had been employed many centuries. Fumigation by means of chlorine, bromine, etc., were regarded as valuable, but of rather minor importance compared with sulphur. In the employment of agents which have since been proved to be valuable, no rules were followed as to proper amount or strength.

In 1881 Koch² demonstrated the unreliability of sulphur fumigations by a long series of careful experiments, begun in 1879, and conducted under the most scientific conditions by himself, Hueppe, Proskauer, Westphal, von Knorre, Platt and Heyde. They proved

¹ Read before the Boston Society for Medical Improvement, April 23, 1888.

² Wolffhügel. Ueber den Werth der Schwefelgase als Desinfectionsmittel. Mittheilungen aus dem kaiserlichen Gesundheitsamte. Bd. I.

³ Mitth. aus d. Kaiserl. Gesundheitsamte. 1881, I, 234.

⁴ Deutsche. Vrtljschr. f. all. Gesundheitsg. 1887, xix, 318.

that the gas is not given off in practice anything like what it should be according to theory, that it is not diffused homogeneously, that it does not penetrate large packages beyond the surface, or the ordinary folds of clothing, and that it does not destroy the vitality of all micro-organisms even under the most favorable conditions when moisture is supplied, in which latter case, too, the articles acted on suffer more or less damage. Their conclusions, published in 1881, were that sulphur fumigations are thoroughly unreliable where there are spores, in whatever manner the process is carried out, nor are they effective against micro-organisms not on the outer surface of infected articles, and that their further employment should be wholly abandoned in favor of such agents and processes only as will destroy all infectious matter without exception.

These conclusions have been endorsed repeatedly by other experimenters, and by scientific societies and sanitary conventions. In spite of all this, however, the sulphur fumigation process still has some friends, and it is even prescribed by at least one municipal board of health. An occasional writer contributes an article in favor of this process, but it is usually to be noticed that he writes not from experiments performed, but from older writings of others, and that he rarely alludes to the fact that the value of the process has been even disputed. Koch³ showed also that zinc chloride, which has been and is now by some regarded as very active and efficient, is absolutely worthless as a disinfectant. Many other agents were shown to be worthless, and others proved to have a much diminished value. In short, the list of effective chemical disinfectants has been narrowed down to a very small number, some of which, for one reason or another, are ruled out for practical work.

At present about the only chemical disinfectants recommended by scientific men for practical purposes are carbolic acid, chloride of lime and corrosive sublimate, and the employment of these agents requires good judgment and a consideration of individual conditions. The value of these compounds has been repeatedly demonstrated, but their use is naturally somewhat restricted, in that many articles, such, for instance, as stuffed furniture, mattresses, outside clothing, etc., cannot always be treated chemically. Fortunately, however, there is a physical means, which, in its place, is of equal or greater value than the chemical agents. I refer, of course, to heat.

The researches of Koch, Wölffhügel, Gaffky, Löffler, Merke, Hueppe and Lassar, published in 1881,⁴ and repeated and endorsed by many others, show that steam is more effective in every way than hot air at 140° C., with much longer exposure. It penetrates bulky articles much more quickly, kills all known micro-organisms and spores within fifteen minutes, and does no damage except to a limited number of articles, such as leather, furs, and veneered furniture.

Heat and the few chemicals mentioned have the approval of the leading scientists of the world, who have abandoned the clumsy, unscientific and ineffective processes long in vogue.

The cholera conference at Rome in 1885⁵ agreed on

the following (among other) rules regarding disinfection. The best disinfectants are steam at 100° C., carbolic acid, chloride of lime, and aeration. (Carbolic acid in solutions of two and five per cent., chloride of lime, one and four per cent.) For disinfection of persons, washing and baths of the weaker solutions. For disinfection of the body, bed linen, etc., the following: 1. Destruction by fire; 2. steam; 3. boiling for thirty minutes; 4. soaking in the weak solutions for twenty-four hours; 5. airing for three or four weeks, but only when other means are not available. Leather articles, boots, trunks, etc., to be destroyed or washed repeatedly with the chemical disinfectants. Vomitus and dejections to be immediately treated with the stronger solutions. Soiled linen, etc., which cannot be immediately exposed to steam, to be soaked at least twenty-four hours in the stronger solutions. These and other rules were adopted for yellow fever and other epidemic diseases. No mention was made of fumigations.

Besides thorough disinfection of the patient, the excreta, the linen, etc., etc., during and after cases of infectious diseases, there remains as a very important part of the process the disinfection of the sick room itself. Fumigations being unreliable and valueless, and steaming being naturally impossible, we must have recourse to some other means. Some experimenters recommend washing and sprinkling of the walls, floors and furniture with corrosive sublimate, or, as recommended by Krupin and Vassilief,⁶ of St. Petersburg, corrosive sublimate and carbolic acid together. Others have suggested corrosive sublimate fumigations, which for obvious reasons are objectionable and dangerous. Others recommend potash soap and carbolic acid for washing floors, and carbolic spray for the walls and furniture. Esmarch,⁷ however, shows that for walls the best method for the removal of infectious material is rubbing them thoroughly with pieces of bread, which process he shows to be efficient, not difficult of application, and unattended by danger. The micro-organisms adhere with great tenacity to the bread, which, with any crumbs which break off and fall to the floor, must be carefully removed and destroyed by fire.

For proper disinfection by steam it is essential that the proper apparatus be somewhere at hand, for without special apparatus the process cannot be carried out. By whom should the apparatus be supplied, and by whom should the process be conducted? Disinfection is more a matter of public than of private interest, and the thoroughness of the operation can best be guaranteed when the process is carried out by competent public authority. It is far better to spend the public money for the prevention of disease than for its treatment. The direct cost may, in many cases, it is true, be less in the treatment than in the prevention of the disease, but in the long run as is shown by statisticians, sickness and death of individuals are a distinct loss to the State. Disinfection should be free to the public, for expense to the individual will always be an obstacle to thorough work. It is true that when a privilege is free it will be abused, and, as has been remarked by Professor Hofmann,⁸ of Leipzig,

dirty clothes not infected may be brought for the sake of the improvement in appearance, and feather beds for the renovation which the steam gives them, but the abuse of the privilege might be very easily kept under control by simple regulations.

Of the apparatus for steam disinfection I will presently speak in detail.

With the few necessary chemical and physical means of disinfection, and the proper apparatus, and with a proper observance of simple rules, there is no reason why disinfection should not be carried out on scientific principles in every city and town. No public health authorities have any right to retain old abandoned processes whose utter unreliability has been proven by the highest scientific authority. If the retention of obsolete processes is owing to ignorance, such ignorance is more than unpardonable; if not due to ignorance, then it must be owing to a disbelief in what every leading sanitarian in Europe and elsewhere has endorsed.

Considering the great strides that have been taken in this subject within the past ten years, it is wrong—and I might with justice use a stronger term—to teach the public a process of disinfection that is worse than useless, in that it leads to a false sense of security, and to compel its employment under heavy penalties. The public should be taught true disinfection, or none. It is difficult at best to educate the public in sanitary matters, but far more so to root out the results of improper teaching.

As a proper method of disinfection, I will instance that adopted by the authorities of Berlin. Disinfection is required absolutely in certain diseases, and conditionally in certain others. The public are taught that thorough cleanliness, frequent airings, speedy removal and destruction of infectious material are most important parts of a whole. It is recommended that the patient be washed daily, and that the body and bed linen be changed as often as once a day if possible. Soiled linen must be changed immediately. The room should be cleansed daily by wiping down with moist cloths, which afterwards must be treated with boiling water for half an hour. The room should be aired frequently and thoroughly by opening the windows. Steam, boiling water, burning, and solutions of carbolic acid, two and five per cent., are adopted as proper disinfectants. All bed and body linen, and all cloths used for wiping down, must be soaked twenty-four hours in two per cent. carbolic, then boiled a half-hour in water, and finally washed with soft-soap solution (twenty grams to ten litres). Infectious dejections, sputa, etc., must be received in vessels a quarter full of carbolic acid five per cent. If the patient should use the water-closet the seat and receiver must be seoured with five per cent. carbolic acid and thoroughly rinsed. Food and drink are not allowed in the sick-room, except as required for the patient alone. Old dressings, etc., are burned, instruments washed in five per cent. carbolic acid, and bad smells got rid of by removal of their causes.

On the cessation of the sickness all unwashable clothing, beds, pillows, mattresses, coverlets, silks, carpets, etc., etc., are tied up in sheets wet with two per cent. carbolic, and taken by the authorities to the public disinfecting station. Valueless material is burned forthwith. Certain articles of ornament and furniture may be wiped down with cloths; and tapestries, hangings, etc., with bread, but the floor must first be

wetted with five per cent. carbolic acid. Any soiled places on the walls (from excreta) are moistened with five per cent. carbolic acid, and scraped off. Floors, doors, windows, etc., are washed thoroughly with carbolic solution, five per cent. The bread and rags used must be burned. When the room with its contents have been well cleansed it must be aired for twenty-four hours. Other rules have reference to the disposal of the dead, and to the attire and personal habits of the attendants, etc., etc.

The articles to be carried to the public disinfection station are called for and returned by the authorities. They are taken away in a closed wagon by experienced men, who during the handling and packing are attired in long linen coats reaching to the feet. On leaving the infected house these coats are sprinkled with carbolic five per cent., folded, and packed with the other infected articles in the wagon. The articles removed are incased in linen wrappers and sacks well moistened with carbolic. Carpets are rolled and not folded, thus avoiding permanent creases which would be caused by steaming. When everything has been packed in the wagon the driver takes the shortest road to the station, and enters the yard on the right (see cut). The infected articles are then unloaded at the platform L, after which the wagon itself is washed with five per cent. carbolic, or corrosive sublimate 1:6000, and stowed in a shed.

Before proceeding to a description of the manner in which the work is done, a brief explanation of the plan of the building will not be out of place.* A is a store-room for coal and a repair shop. B is the boiler room, containing two boilers, in which the steam is kept under a moderate pressure. C and D are bath-rooms and water-closets for the attendants. E is a store-room for chemicals. The steam passes from the boilers to the apparatuses a, a, a, from which it es-

* I am indebted for the plan, description, etc., to the article by H. Nerke. Die erste öffentliche Desinfections-Anstalt der Stadt Berlin. Vierteljahrsschrift für gerichtliche Medizin und öffentliches Sanitätswesen. Bd. XLV., p. 127.

capas to the chimney F. The articles to be subjected to steam are loaded into the apparatus in the room G 1; previous to this operation they are stored in the room J, which is well provided with racks, shelves, hooks, etc. After the operation of steaming is finished the articles are unloaded from the apparatus in the room G 2, and are stored in H, which is similar to J. There is no possibility of re-infection of the disinfected articles in H by infectious material in J or G 1, as there is no communication between the two sides of the building. K is an office, which is shut off from H and J excepting by two windows, of which the one looking into the store-room for infected articles (J) is hermetically sealed. Communication between J and K is by means of a telephone. Disinfected articles are loaded into another special wagon, at the platform M, and are carried away through the yard on the left.

The process of steaming as carried out is briefly as follows. The articles are loaded into trucks or cages which run into the apparatus a, a, a, the doors of the latter are then tightly closed. The steam is turned on for thirty-five minutes, at the end of which time the apparatus is ventilated for ten more. The attendants in G 2 are then notified by means of a bell that the apparatus is ready for unloading. This is done, the doors of the apparatus opening into G 1 remaining closed until the bell again rings, which is a signal that the trucks have been replaced, that the doors into G 2 are shut, and that the next loading may be begun. When steaming is in any case contraindicated the disinfection is carried on in the usual way with chemical washes.

Many other cities of Europe have these stations for steam disinfection, and there is no reason why we should not have them in this country. It would, of course, be unreasonable to require small towns to provide such elaborate systems, and it would be also unnecessary. Portable steaming apparatuses have been devised for use in small towns and thinly-settled localities, so that proper disinfection is everywhere possible at a very moderate expenditure for transportation, labor and fuel.

REPORT OF PROGRESS IN ORTHOPÆDIC SURGERY.

BY E. H. BRADFORD, M.D., AND R. W. LOVETT, M.D.

POTT'S DISEASE.

DR. ALEXANDER's paper¹ upon "Some Points in the Pathology and Treatment of Caries of the Vertebrae," is a careful study based upon the post-mortem observation of 53 cases of Pott's disease, 5 were cervical in location, 20 dorsal, 20 lumbar, and 8 dorso-lumbar; of the 28 dorso-lumbar cases it was the lower part of that region that was affected. From his cases he concludes that the origin of most cases is either traumatic or pyemic. Half of these cases appear to him to have been traumatic. To the word pyemic he attaches rather a peculiar significance. When spinal disease comes on secondarily to hip disease, to scrofulous abscesses or bone caries, etc., he believes it due to purulent infection, and these are the cases which he calls pyemic.

Cure takes place sometimes by true anchy-

losis between the bodies of the vertebrae; this, unless it occurs at a very early stage of the disease, before much deformity has taken place, is not to be desired, because, a case with great deformity means a shortened life oftener. 22 of these 53 cases died at adolescence, and the average age of cured cases is not twenty years. But oftener than by anchylosis of the bodies a cure takes place by anchylosis of the abnormally pressed together articular processes and the approximated pedicles, and in all cases the first out-pouring of inflammatory tissue takes place here; and he speaks of a case where the bodies were only partially anchylosed, but where the pedicles, laminae and spinous processes were so finally anchylosed that they had to be removed in a solid mass. And this latter is the anchylosis that Dr. Alexander considers the more desirable by far, and the one to be aimed at by antero posterior splints and fixation. He comments upon the very long time necessary for a cure, and speaks of the great harm done by accepting a cessation of symptoms as an indication for discontinuing treatment.

Fleming² advocates the treatment by rest in bed and extension of a certain number of cases of Pott's disease "not suitable for any of the varieties of jacket treatment." His particular method deserves a word of description. The patient wears a Sayre head sling, attached to the head of the bed by rubber tubes which are constantly on the stretch. Counter extension is obtained by a broad towel tightly pinned or sewn around the pelvis, to the middle of which behind is attached a stout calico bandage, and this is fastened to a weight and pulley extension at the foot of the bed. The patient lies on a smooth rubber sheet dusted with boracic acid.

HIP DISEASE.

H. L. Taylor³ describes for the first time a very efficient splint for overcoming adduction in hip disease, either when in the acute stage of the disease it is produced by muscular spasm, or after a cure has resulted, it returns and makes locomotion difficult. The splint is an inside extension hip splint, with the usual foot-piece, applied along the inside of the diseased leg, bearing, however, in the opposite groin by means of a perineal band hung from properly shaped arms. When applied and tightened adduction is necessarily counteracted, and the reduction of a very considerable deformity should be only the matter of a few days or weeks. Extension is obtained, as in the ordinary hip splint, by adhesive plaster applied to the leg. The apparatus is to be worn in bed, and after the reduction of the deformity a retaining abduction crutch is to be added to the ordinary walking splint.

OPERATIVE TREATMENT OF JOINT TUBERCULOSIS.

Gerster⁴ writes of "The Modern Operative Treatment of Tubercular Joint Affections," and first, speaking of the importance of the ice bag as an adjunct to fixation and rest, he says that not only does it give relief to a hot and tender joint, but that even the progress of the disease may be retarded by its use; and Koch has demonstrated by experiment that extraordinary sensitiveness of the tubercle bacilli to temperature changes, so slight a change as two degrees centigrade below the normal of the body being enough to arrest

⁴ Gerster. *Ann. of Surg.*, April, 1888, 241.

their propagation. It would not, of course, affect the spores, it would only arrest the progress of the disease temporarily, so that one might, in the meantime, give effective local and general treatment.

"The other form of curative and preventative therapy consists in the early ferretting out and surgical evacuation of tuberculous cheesy foci located in the epiphyses of the bones entering into the formation of this or that joint." And discussing the field of mechanical treatment of these affections, it seems as if in tuberculous affections of the joints of adults (mostly in bad circumstances and very likely with phthisis) early excisions were indicated to the exclusion of other treatment as a rule. In children, however, mechanical treatment should be faithfully tried, abscesses should be tapped and injected with iodoform and ether, and finally, if all these measures prove useless on account of inefficient care or virulent disease, operative treatment must be resorted to.

And some of the chief precautions laid down are that all tissue diseased or even morbidly altered should be most conscientiously removed, that in children where the trouble is circumscribed and limited to certain parts of the joint only, the diseased parts should be removed, and that so far as possible the risk should be avoided of what König calls the "operative dissemination of tuberculosis" through the circulation; which means that the Esmarch bandage should be used when possible, that the knife should do the work of the elevator and curette, and that irrigation should wash away the debris.

The after-treatment is determined by the factor whether one wishes mobility or ankylosis in a given case. If the former is desired the splints should be removed, as in the elbow, for example, as soon as the incisions are healed, and the gentlest of passive motions begun at four or five weeks after operation. In the hip a Taylor splint should be worn at least a year, and many other details of after-treatment are given. And, finally, in unsuccessful cases, amputation should not be delayed until it is too late.

ARTHRECTOMY.

Tilling⁶ has attempted to resect the joints saving the joint ligaments as far as possible, chiselling out the muscular insertions and the ligaments, and after resection of the bone securing by nails the separated ligaments again on to the bone.

The reporter has operated five times on the knee. A cross-incision is made down to the ligament of the patella, and this is freed not by cutting but by chiselling off the tuberosity of the tibia. The same thing is done with the epicondylis. The crucial ligaments are then divided, and the diseased portion of the bone removed. The separated fragments of bone, with the adherent ligament are then secured to the sound bone by means of ivory pegs.

In the hip-joint the trochanter major and the adherent tendons are chiselled off and again nailed to the shortened shaft.

In resecting the ankle-joint the malleoli are removed by chiselling from above downward, and the ligaments and tendons spared, the incision through the skin being a curved incision with the convexity upward, arching obliquely over the tips of the malleoli. The shoulder and elbow joint are resected in the same way.

* Centralblatt f. Chirurgie, Jan. 28, 1889.

RESECTION OF THE WRIST.

Gangolphe⁶ reports an autopsy on a case dying of tubercular meningitis three years after excision of the wrist. A perfect recovery had taken place at the wrist. The space between the metacarpus and upper arm was composed of fibrous tissue, with a few bony substances scattered through the tissue. The joint was during life quite useful. The results are, according to Gangolphe, most satisfactory between the ages of thirteen and eighteen.

LATERAL CURVATURE.

The mechanical theory of the production of scoliosis is vigorously attacked by Mr. Keetley.⁷ First, he compares the section of a vertebra from a lateral curvature, and the epiphysis from a case of knock-knee, and comments on the similar wedge shape of the two. This wedge shape, he says, "has been found in every specimen of scoliosis, mild or severe, in every museum in the world in which it has been looked for;" and he assumes that therefore this shape exists at the very onset of the disease, and is the primary affection. He next attacks and disposes of the three supposed features in the production of the deformities on the mechanical theory: (1) muscular weakness, because muscular weakness by no means always exists with scoliosis, and because of the host of muscularly weak people only a small, a very small proportion have lateral curvature; (2) inequality in the length of the limbs; and (3) the practice of carrying weights on one shoulder or one arm, he disposes of in the same way.

So much for the destructive part of the paper, the constructive part advocates rachitis or an analogous bone disease as the cause of most cases. The deformity occurs almost always during early childhood or "between the age of eight and sixteen. In the former case its rachitic origin is undoubted." (?) In the latter case he is inclined to associate it with faulty hygiene, insufficient nutrition and consequent bone change. "The various influences which may injure the constitution during infancy and youth act at least indirectly as causes of scoliosis by predisposing to or actually producing rachitis, either in infants or adolescents, and possibly in other ways." Finally he asserts that scoliosis occurs in animals, and cites the instance of a scoliotic gold fish alive in the West London Hospital. The article bears evidence of such hasty and loose writing that it loses much of its value.

Mr. Barwell⁸ summarizes in a very interesting way his different methods of treating lateral curvature, whose object, as he expresses it, is to "lead the spine aright, rather than to force it into this or that attitude." For mild cases, due to pelvis abliquity, he corrects the obliquity by inequality in the soles of the shoes when on the feet, by sitting down on a sloping seat only, and by lying for a while in bed each night with a raised sling under the convexity of the curve. In the next grade he uses what he calls the "loin bandage" which is a swathe going around the crest of the ilium on the side that he wishes to depress, which is pulled down by a perineal band in the other groin, which is attached to a band encircling the leg. This is worn during the day and each night the patient lies for a short time on the raised swing mentioned

⁶ Revue de Chirurgie, No. 9. Centralblatt f. Chir., Feb. 4, 1888.

⁷ Annals de Surgery. Feb. 1888, p. 126.

⁸ R. Barwell. Lancet, July 9, 1887, p. 59, and August 13, 1887, p. 301.

above. A girth is also attached to a staple in the wall and applying this girth to the convexity of the curve the patient leans sidewise so as to bring the weight of the body largely on the girth; in addition to this he would apply in severe cases his well-known dorso-lumbar bandage. So much for the treatment of the lateral part of the curvature.

For the rotation, he applies a modification of his dorso-lumbar bandage in severe cases; whereas, in mild cases, he makes use of the arm to antagonize the action of the serratus magnus, by having the patient in cases with slight dorsal curvature, for example, carry the left arm behind the waist and by wearing a lead strip on the left arm weighing some four ounces. He also directs the patient to rest the erector spinal muscles several times each day by lying flat on the belly with a pillow under the chest. With this treatment he would expect to prevent a beginning case, to cure other cases in the first or second stages (unless from severe rachitis or lung consolidation) and even in the early part of the third stage, as he divides the disease.

SCHOOL-DESKS.

Lorenz,⁹ after a careful consideration of the various plans suggested for school-desks, and the various seats in use, concludes as follows: "To avoid the dangers of scoliotic attitude resulting from fatigue and the scoliotic position assumed in writing, a back support to the chair inclined 10° to 15° backward, with support for the back, is of importance."

This conclusion practically coincides with that of Kocher,¹⁰ who advises proper school-seats as of the greatest importance in the treatment of lateral curvature. Kocher recommended the seat advised by Schenk,¹¹ which is designed to support the back, even while the child is writing. The back of the seat is inclined backwards at an angle of 15°. The desk should be 12 cm. higher than the seat, and the latter should not be separated more than 18 cm. also from the desk.¹²

SPINAL SUPPORTS.¹³

Beely recommends as a substitute for the plaster jacket cloth corsets modelled on plaster casts, and strengthened by steel strips carefully made and modelled.

Staffel¹⁴ recommends, to prevent stooping in writing, a strap at the level of the forehead, connected with two uprights fastened to the desk; the back is supported by a pressed plate in the lumbar region.

BOW-LEGS AND KNOCK-KNEE.

Stillman¹⁵ describes a new brace for bow-legs, dependent for its efficacy upon a couple of metallic springs pressing upon the convexity of the curve; in other respects, it is very much like the ordinary braces. In one respect it has a desirable addition in ratchets below the ankle-joint, so that the foot may be inverted or everted in its relation to the leg if desired. Figures of the brace are given in the article.

A. S. Roberts,¹⁶ in two clinical lectures recently delivered, classifies bow-legs and knock-knee as due to

one of three causes: (1) Rachitis; (2) ligamentous relaxation; and (3) central disturbances, as poliomyelitis, etc. As to the bone changes resulting from rachitis, he divides them into three stages: (a) stage of vascularity, (b) of softening, (c) of sclerosis. In the last of these stages he considers mechanical treatment as useless, and resorts at once to operative treatment, and he prefers osteotomy to osteoclasis. He ascertains where sclerosis is present by the use of a bone drill. Where it encounters no obstacle in entering the bone he uses mechanical treatment; but where, on reaching the bone, it meets with sudden resistance, as if being bored into ivory, he resorts to operation.

The brace which he uses in private and hospital practice for bow-legs "consists of a piece of straight-tempered steel, its upper extremity terminating in a semi-circular steel band to extend half around the leg; below, and jointed to it opposite the ankle, is a steel foot-piece with heel-cup, which is secured to the foot by a strap passing over the instep, and a light leather shoe laced over the foot. . . . The brace is adjusted by securing it to the internal aspect of the limb, and the elastic element of the brace brought into play by strapping the steel upright to the leg at the point of the greatest convexity. It should be thus applied at night." For knock-knee, he uses a similar brace applied to the outside of the limb. The details of the operation of osteotomy are given very clearly.

Brown¹⁷ summarizes his experience in much the same way, but in favor of osteoclasis, of which he gives a very full history, and enters into the details of the operation, giving both the manual and instrumental methods. In rachitic deformities he would only do an operation after the bones had become eburnated, and the principles of treatment which he advocates are as follows: (1) In children under two years of age, in which the deformity is not exaggerated, the expectant plan, possibly with frequent daily attempts at correction with the hands. (2) In older children, in which the bones are yet soft, some form of mechanical support. (3) As soon as the bones become eburnated, osteoclasis or osteotomy. (4) Osteoclasis is to be preferred in all cases of deformity near the middle or long bones, in a large proportion of cases of knock-knee and other deformities near the joints, and only rarely in bony ankylosis and club-foot.

OSTEOTOMY.

Motta¹⁸ reports a summary of the work of the late distinguished Italian surgeon, Margary, who performed osteotomy a large number of times, 361, preferring MacEwen's operation to *brisement forcé* or osteoclasis. He has performed as many as six osteotomies on one individual at one sitting. The results were eminently satisfactory in all cases. In six cases of ankylosis of the knee-joint in an abnormal position, preferring osteotomy, either simple or wedge-shaped, to resection. If, however, there is slight mobility at the knee, he prefers resection, in order to prevent relapse.

OSTEOCLASIS.

Buttersack¹⁹ has made some experiments on the cadaver with Robin and Collins's appliance, modified by Beely, his results corresponding with those of Pousson and Demons.

The advantage of this apparatus is that the fracture takes place at the desired point of the bone, even if it is near the joint, and without injury to the joint ligaments or injury to the soft parts.²⁰ The writer prefers this method to osteotomy. The objection to the procedure is the complicated nature of the appliance.

Ferrari²¹ describes Collin's apparatus, and recommends its use in knock-knee. Collin's own appliance is even more complicated than that modified by Beely. Ferrari uses, also, a simpler one devised by himself, resembling a Rizzoli's osteoclast, with the addition of pressure-plates, and instead of the rings used in the latter, he uses one ring for counter-pressure, and two pressure-screws with broad plates for direct pressure.

FLAT-FOOT.

Roth,²² speaking of the causes and treatment of flat-foot first calls attention to the fact that in every three cases of lateral curvature of the spine two suffer from flat-foot, and that it very often is associated with knock-knee is well-known. The treatment should be the restoration and maintenance of the depressed plantar arch and the strengthening of the leg muscles which tend to produce and preserve the normal arch of the foot; these are of two kinds, mechanical and therapeutic. The simplest mechanical treatment advocated, is a broad laced boot with low heel, and a support in some cases to the arch by a pad of superimposed layers of felt. Also the sole is thickened on the inner margin of the heel and sole. The severest treatment advocated is "*brûlément forcé*" by Mr. Thomas's wrench, under anesthesia.

The most interesting part of the article lies in the medical gymnastics described in detail by M. Roth, which unfortunately cannot be given in detail here. They are simple exercises directed to the strengthening of the faulty muscles, and in one or two weeks he begins to notice the benefit from treatment.

(To be continued.)

Clinical Memorandum.

CHRONIC INFLAMMATION OF THE SPERMATIC CORD. SURGICAL INTERFERENCE.

BY HORATIO H. JOHNSON, M.D., BELFAST, ME.

Mr. P., aged seventy-five years, a stout, hardy farmer, seven years since noticed a swelling in the groin, which he supposed to be a "rupture," and without any surgical advice applied a home-made truss which at times made him so sore, and gave him so much pain that he would be obliged to discontinue its use. On November 4, 188-, he was in such condition that he sent for medical advice, and the physician recognizing the necessity of surgical interference, on the following morning I received a telegram to see the patient in consultation. I found a hard, unresisting swelling, extending from midway between the superior spinous process of the ilium and the symphysis pubis, down to the testicle, which was considerably drawn up in the scrotum. The bowels had moved regularly each day, unaided by laxatives, which led me to judge it was not a hernia, though previous to my visit the

patient had been etherized and taxis had been thoroughly tried. The case was diagnosed as chronic inflammation of the spermatic cord, and it was deemed prudent to resort to surgical means for the patient's relief. Assisted by Dr. George C. Horn (the anesthetics being under the charge of Dr. P. P. Nichols, dentist). I removed five and one-half inches of the spermatic cord, with testicle attached, ligating above all signs of disease. The cord measured seven inches in circumference, and was well advanced toward suppuration. The patient was confined to his bed about five weeks, with very little rise in temperature or acceleration of the pulse, and the wound healed mostly by first intention. The ligation on the pedicle remained twenty-five days. The patient is now about, and has made a complete recovery from the operation. I considered the diseased mass the result of continual irritation from the wooden pad worn for supposed rupture.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

F. B. HARRINGTON, M.D., SECRETARY.

REGULAR meeting, Monday, April 23d, at Medical Library, 19 Boylston Place.

In the absence of the President, Dr. S. W. Langmaid was made temporary chairman.

Dr. R. H. Fitz read a paper on

THE ORIGIN OF TYPHOID FEVER IN HOSPITALS, AND THE MEANS SUGGESTED FOR ITS PREVENTION.¹

Dr. Folsom: I regret to say anything to the Society before having reached more definite conclusions than I have in my own mind. I made an investigation at the City Hospital with regard to the number of cases of typhoid fever which have occurred there from the beginning of 1884, until the present time, the method which I took being as follows: I examined the records of those years, some fifty volumes in all, looking over the report of every case of typhoid fever and consulting the indices which are kept in this way. Under the head of diagnosis is the name of the primary disease for which the patient came to the hospital, and in a second column the name of any other disease occurring during the patient's stay at the hospital. During that time I found that there were twenty-eight cases of typhoid fever which occurred among the house officers and employees of the hospital, and one case, which is of very doubtful origin, in a patient. I looked over the records carefully in reference to that point, and have inquired of the house officers and physicians and Dr. Rowe. I cannot ascertain that there has been a single case of a patient contracting, or probably contracting, typhoid fever in the hospital during that time; and it should be recollected that there are seasons of the year when the number of patients with typhoid fever make about one-third of the total number of patients in the medical wards. At one period in 1886, during the latter part of my service, the large female ward with twenty-eight beds contained eleven patients with typhoid fever. Dr. Rowe reminds me that during that season there were

²⁰ Centralblatt f. Orthopädische Chir., January 1, 1888, with illustration.

²¹ Centralblatt f. Orthopädische Chirurgie, January 1, 1888.

²² N. Y. Med. Record, March 17, 1888, p. 299.

¹ See page 513 of the Journal.

five continuous weeks during which the number of patients with typhoid fever was never less than sixty-five.

I will not read the records of these twenty-eight cases; I will only say that I have been over them myself very carefully, and that I am satisfied that there is no doubt of the diagnosis of typhoid fever. During the year 1887, two nurses employed in the wards of the Hospital, the medical wards, had typhoid fever, also one boy who washed windows, and two medical house officers. In 1886, there were five nurses, three ward-maids, one ward-master, one woman employed in the kitchen who did not come in contact with the typhoid fever patients, one of the house officers who had been on a vacation to Cape Cod, and who himself attributes the origin of the disease to his vacation, and one of the laundresses; twelve in all. In 1885, three nurses, one ward-master, and one ward-maid. In 1884, four nurses, one laundress, one window-boy, and one patient, whose history was as follows: He came into the Hospital with subacute rheumatism. After he had been in the ward two weeks his temperature began to rise, and five days after that, that is, on the nineteenth day after he came in, he had the high temperature of well-defined typhoid, 104° in the evening. That is to say, in this period of four years, there were two window-boys, two ward-masters, two laundresses, two house officers, four ward-maids, one kitchen maid, and fourteen nurses, besides the patient with regard to whom the origin of the disease was quite doubtful, and the doctor who thought that he took his disease outside.

Going back as many years as I can recollect, and as far as those gentlemen could whom I have asked, I cannot find that any of us can recall a single patient in the medical wards who even probably contracted typhoid fever while in the wards. There were two surgical patients, one of whom contracted typhoid fever two weeks after he entered the hospital—a little less than two weeks—which was at least a doubtful case, especially as he did not come in daily contact with any of the nurses who were taking care of typhoid patients. Dr. Rowe recalls a surgical patient in '81 or '82 who contracted typhoid fever a number of weeks after he came into the hospital, but he was in a surgical ward, and was not brought in contact with typhoid patients, or nurses taking care of typhoid patients.

It certainly is very extraordinary that during this period of time, especially when there were eleven out of twenty-eight in one ward, and sixty-five patients for five weeks continuously, and when, for a very considerable portion of the time, nearly one-third of the medical patients were typhoid, it is certainly very extraordinary that we have not been able to find any reports of any patients acquiring the disease, although at that time there were always debilitated patients whom one would think as liable to contract the disease as nurses, if they were exposed.

I have looked over the records carefully, and unfortunately none of them state clearly enough what the patient was doing for the previous three weeks to enable one to make even a guess as to the probable place where the disease originated. That does not occur in a single case. A certain number of records of cases speak of the nurse as being very hard at work, as doing night work, etc., but nothing is said to indicate whether or not there was any possibility or prob-

ability of the fever being contracted elsewhere. In looking over the records of one of the nurses, as it occurred to me that the case might have originated in the hospital, I turned over to the record of a preceding page, which was of a nurse in the infant asylum in Brookline, in regard to whom there was just as much evidence that the disease originated in the asylum as the other in the hospital. That is to say, the evidence, so far as the hospital in these years is concerned, seems to me not conclusive, although the fact that so many nurses contracted typhoid fever is certainly suspicious; that is to say, fourteen nurses, or one-half the total number of cases which I have reported.

With regard to the length of time from the introduction into the system, either by the lungs or stomach, of whatever it is that causes the disease, until the actual appearance of symptoms of the disease, of course that time varies very much indeed, and of a very large number of persons exposed to the same conditions, the period of the outbreak of the symptoms varies very much.

The cases, to which Dr. Fitz referred are very interesting from that point of view. I refer to those from the steamship *Prussian*. The facts were examined very carefully by Dr. Russell, the health officer of Glasgow, and he is reported as having satisfied himself that the emigrants were exposed in very large numbers to typhoid fever in an emigrant boarding-house before going on board the vessel. If that is true, and Dr. Russell's reputation is such that we may assume that it is so, and if that were the only source of infection, the period of incubation, if we may call it such in these emigrants, varies from ten days to between four and five weeks; so that, in the analysis of the origin of our cases of typhoid fever at the city hospital, there is a great deal of embarrassment. As every single one of the cases was going out of the hospital frequently, almost daily, and to parts of the city which might have been infected, I think that from these statistics, it is impossible to draw definite conclusions.

In regard to the danger of conveying the disease from the fresh dejections, of course as we all know, there are two very different theories. Pettenkofler, who for many years was chairman of the National European Cholera Commission, and who certainly has investigated cholera and typhoid fever carefully, is firmly convinced, and his pupils are also firmly convinced that it is impossible to convey the disease by any fresh poison. I have no opinion to offer on that point. I regret that I have not been able to say something more definite, but I have been obliged to adhere to the facts as they have presented themselves.

The President then called for the paper by Dr. Charles Harrington on

PROPER AND IMPROPER METHODS OF DISINFECTION.²

The discussion was then continued.

Dr. G. H. M. Rowe said: It has been a matter of much solicitation to myself, as well as to the Superintendent of Nurses, in regard to the cause of typhoid fever whenever it has occurred to nurses or employees at the Boston City Hospital. Capt. Douglas Galton, a recognized hospital authority, makes this statement: that he does not believe in the contagiousness of typhoid fever in the ordinary sense,

² See page 616 of the Journal.

and that if a case occurs in the nursing force of a hospital it should be laid to the habitation of the nurse, and not to her association with the patient. Previous to September, 1886, the nurses at the City Hospital Training School, who then numbered about sixty-two, were lodged in rooms in various parts of the Hospital buildings. About half were in the third stories of the new medical and surgical buildings, and the remainder in (so-called) nurses' rooms, which adjoined the medical, surgical, and contagious wards. In the last week of September, 1886, the Nurses' Home was opened for occupation, with accommodations for sixty-seven nurses. I think it is safe to say that the sanitary conditions of our Home are of the best, and as good as can be found for an equal number of nurses.

The plumbing is of the most approved systems, the heating is by indirect, supplemented by direct radiation and fireplaces; every room in the Home is ventilated, independent of other rooms, and there is a ready exchange of air. The arrangements for personal hygiene of nurses are most excellent. The largest number of cases, as Dr. Folsom has related them, occurred previous to the opening of the Home, and this fact bears upon statements of Capt. Douglas Galton that the habitation may have much to do with the matter of typhoid among nurses.

As to the class of nurses who have had typhoid, I may say that it has occurred more frequently among those who have worked in medical wards, and largely among the night nurses. Gentlemen attendant on hospitals will recall the fact that during the day the nursing is divided among several nurses, say five in a ward of thirty patients. But when the night nurse comes on for eight hours' consecutive work, she has the care of all the patients. Therefore, the risk, whatever it may be, is much greater in her case, other things being equal, than where it is distributed among five day nurses. The fact that the night nurses have suffered in a larger proportion may be attributable to this concentration of contact.

If typhoid fever rises directly from contagion and contact to the germs of that disease, it would seem to raise the query whether or not, in a large hospital averaging for consecutive weeks sixty-five cases or more, certain classes of workers other than nurses should not be affected. During the year, the daily and weekly work of keeping the house clean and in good order is done by a permanent force of scrubbers, ward-maids, window-boys, and the like. But from the first of May to November there is employed a corps of "house-cleaners," as they are called, consisting of eight women and two boys, who do nothing else than "house-clean," as that term is usually used.

I don't recall an instance of any house-cleaner who has been ill with typhoid or any contagious disease. This gang of women have to wash and carbolicize all portions of the establishment: they dust and wash all the ledges, covings, and high portions, which in many places are crowded with dust. It would seem that this class of workers would become affected. I know of only two instances where laundresses have been ill with typhoid fever, although the amount of bed-linen and other clothing that comes from sixty-five typhoids is, of course, very large.

In regard to the precautions and measures used by us: The nurses are instructed to pour carbolic solution, 1-40, into the bed-pan before it is put under the patient. After the defecation, the bed-pan is covered

with a rubber cover in its passage from the bed to the slop-hopper. Carbolic solution, 1-20, is poured into the bed-pan. The slop-hopper is first flushed, and then the bed-pan is emptied and thoroughly washed and carbolicized: it is then placed in a rack against the wall, with the point downward, so as to hold fresh carbolic until again used. The hopper is flushed, and solution chloride of lime poured in. The bed-linen, when removed, is taken immediately to the basement and put into galvanized iron barrels, and carbolic solution added. This barrel is removed to the rinse-house morning and night. The rinse-house is a structure independent of the laundry, and disconnected from any part of the Hospital. There the bed-clothes and infected body-clothing are put into large soapstone receptacles, soaked four hours in solution chloride of lime, one pound to gallon, diluted, of course, by water. Then, after soaking and boiling and thoroughly rinsed, the clothes are removed to the laundry and treated as ordinary clothing.

We do not cover our mattresses in typhoid cases with rubber sacks, but always place rubber sheeting under the bed-sheet. This we have done to save expense. It is questionable if rubber sheeting is not often conducive of bed-sores, and in typhoid patients the greatest care must be taken to prevent bed-sores.

As to the disinfection of wards which are occupied all the year, it is a difficult matter. Where contagious cases are in isolating-rooms, of course it is an easier matter. Before we had our new wards for contagious cases, we have been obliged to treat all contagious diseases in a mixed ward; of course, treating each disease in a separate room. In such wards, fumigation is done at very frequent intervals, consistent transfers being constantly made, in order to make the rooms available for cleansing, and every week two or three rooms are disinfected. We use the process so commonly prevalent, and which, according to Dr. Harrington's views, presented this evening, is a fallacious one, the fumigation by sulphurous acid gas. As in our old wards, where such cases were formerly treated, the rooms were constantly changing in the complexity of cases and character of the occupants. I am not prepared to say that in a room which had been used, say for scarlet fever, subsequently disinfected, and then used for diphtheria, the disease may not have been passed from one patient to another. In the year 1883, when we were crowded beyond safety, and the complications were unusually trying, there were nine patients, all children, admitted for one contagious disease, who in some manner subsequently contracted another, and of these cases three died. It was the publicity of this dreadful state of affairs made to the City Council that woke them, after several years' demanding, to give an appropriation for the two new buildings which are such a relief to us in our work.

DR. DUGGIN said: I have very little to say. I have been very much interested in the papers, particularly the paper read by Dr. Fitz, in which he gives his view of the stage of incubation of typhoid fever. It was somewhat interesting to me when the patients from the steamer *Prussian* landed in Boston, and were seized with typhoid fever. It seems to me that in these cases it is very hard to establish the point of contact with the previous case of typhoid fever. The steamship was about ten days in crossing, and it was about two days after her arrival here, and the landing of the emigrants, before any case of typhoid fever ap-

peared. That would make twelve days at least, and I think that some were seized with the disease about two weeks later, which would make, as Dr. Folsom said, between four and five weeks of incubation, provided the contact was on the other side of the water. The fact was established that none of the emigrants who came from Glasgow were seized with the fever. I think about one hundred of those coming from Londonderry and Galway were seized with the fever.

It is quite possible that some one of the passengers may have had the disease in so light a form on the vessel coming across that it passed unnoticed, and still furnished the point of danger to the other emigrants. It is quite possible, also, that some one who was ill here in Boston, furnished the contagion after leaving the vessel.

I have been interested, also, in the paper on disinfectants. Many so-called disinfectants have been found, upon careful examination to be only antiseptics or deodorants, and their use abandoned as soon here as elsewhere; in fact, the general use of superheated steam and bichloride of mercury, the leading disinfectants of the day, was adopted in Boston sooner than by any other health organization in the country. We have not been slow to consider the value of sulphur dioxide as a disinfectant, and have had the records of scientific experiments and a long experience to aid us. It is not true that all scientific gentlemen have abandoned its use or ceased to recommend it. We do not claim that sulphur dioxide will kill the spore-bearing germ, and do not use it for that purpose; but we claim that the experiments of Koch, Wolffhugel, Vallin, Sternberg, and others, show conclusively that this agent, when used properly, destroys the disease germs in the absence of spores, and Sternberg makes the statement that there is good reason to believe that the spore is not formed in cholera, yellow fever, small-pox, diphtheria or scarlet fever.—These experiments with sulphurous acid gas coincide exactly with the large practical experience of sanitary organizations throughout the country. These exact tests have shown that a larger percentage of the gas and a longer exposure than were formerly used are necessary, and have given a scientific backing to one of the most common and practical disinfectants known.

If you have a ship or a dwelling-house to disinfect you need a gaseous agent, and the sulphur dioxide is the most practical. If articles of bedding, clothing or furniture have been badly soiled or deeply penetrated by the infection they should be boiled, burned, or treated with some powerful agent, but much of the material found in the sick chamber has but a superficial infection, and may readily be disinfected with the room itself.

It seems to me that the carting away of bedding, clothing and furniture through the streets to a disinfecting station is clumsy, expensive and dangerous, and not likely to be adopted.

The rubbing of the walls, etc., with bread, on a large scale, is not likely to attract serious attention.

DR. BOWDITCH: As a matter of record, I will mention two cases that have occurred in my term of service during the past two years at the Carney Hospital, in two persons who had been there a number of years before the onset of the disease. One was a case of so-called nervous prostration, and she went through the regular course of the disease, with the characteristic symptoms. This patient was in a room

off the general female ward, where there had been several cases of typhoid fever. The other was a surgical case, also off the general ward, where there were several cases of typhoid fever, or had been several weeks before, and she, after recovering from the surgical trouble, also developed typhoidal symptoms. These are the only cases that I know of in my experience in the hospital during the last four or five years. I know of none having occurred in the attendants.

DR. PRINCE: I wish to say two or three words, one in connection with the hospital, and the matter of disinfection. It is a question in which I am very much interested, and I have, for the Board of Health, been making a series of investigations into the origin of typhoid fever in this city. In this way I have been brought in contact with the practical side of the question, and have been occupied in cross-examining patients, and attempting to find out the origin of the disease. Many of these patients whom Dr. Folsom has spoken of I have personally cross-examined myself, and if he has found difficulty from reading the Hospital notes in determining the cause of many of these cases, I can only say that I have found equal difficulty from the direct examination of the patients themselves. I am sorry to say that I have not my notes in a ship-shape form, such a form as would enable me to draw exact conclusions. I am still at work upon them. They allow me to draw certain provisional conclusions, which I will not go into here, because it would take us too far. But I think there can be no doubt that a certain number of cases do arise from the hospital, a certain number from contagion. They occur outside as well as inside. But, as Dr. Folsom said, we should be cautious about attributing them all to the hospital. My experience with the manner in which disinfection is usually carried out has been amusing. In going around from house to house, I have been told often with a great deal of exultation that the people were using all the precautions necessary, and were using disinfectants in the most thorough way. On inquiry I find that it consists, as a rule, in sprinkling carbolic over the floor, and hanging up sheets saturated in the same, or putting chloride of lime in saucers in various parts of the room. I am sorry to say if I am to believe the statements of the people concerned, that the medical profession is at the bottom of it. They say that they do it under the advice of their medical adviser.

In regard to the efficacy of such a process, I confess that I am somewhat surprised at some of the statements of Dr. Harrington. I agree with him that there can be no question that from the time when Koch made his experiments rational disinfection was put on a new basis, but I think we should also be careful in drawing too sweeping conclusions from these experiments. There can be no doubt that Koch's experiments have shown that bacteria containing spores are not destroyed by sulphurous acid gas, as Dr. Durgin said. What they do not show is that bacteria not containing spores are not destroyed. On the contrary they show that the micrococci are completely destroyed by the gas. Koch himself, for example, hung up a thread soaked with anthrax blood, in a box, and after fumigating he found that those bacteria not having spores were thoroughly destroyed. Vallin has found that he has been able to destroy the virus of vaccine. Sternberg has continued the experiments of Koch, finding that bacteria that contain

spores are not destroyed, while those that do not contain spores are destroyed. These results were obtained from experiments performed in the laboratory. It has been shown that it is very difficult in an ordinary room of a house, to maintain the conditions in such a way; that is to say, to maintain a sufficient saturation of the sulphurous acid gas to completely destroy the micrococci without spores. On the other hand Sternberg, in conjunction with the Brooklyn Board of Health, performed a series of experiments, using for the purpose the micrococci from septicaemia and vaccine, to test the value of sulphurous acid gas. Strips of blanket, saturated with septicaemic blood, were placed about the room; one piece was placed on the floor of the closet, another between the mattresses, another was hung to the top of the window, and another to the top of the door. One piece was retained as a control. Sulphur was burned in that room for eleven hours. At the end of that time the pieces were soaked out in bouillon, and the bouillon injected into rabbits. The rabbits injected with the control piece of blanket died of septicaemia. All the others lived except the one piece marked No. 4, which was a piece of blanket folded up and matted together by the blood, so that it is presumed the spores could not be reached. Two virus quills also were taken, split in halves, one-half of each subjected to the gas, and the other half retained. The virus that was not subjected to the gas took, and the other failed to take.

In these experiments there are, of course, certain fallacies. It would have been better, if, instead of using rabbits, they had used cultures, but still they are of considerable value, and form a problematical proof, to say the least, that it is possible to destroy the micrococci without spores by sulphurous acid gas; and the logical deduction from the experimental evidence should be, that in practice we should endeavor to so arrange the room to be disinfected that the conditions shall be identical with those of the laboratory experiments.

The question then arises whether the bacteria of scarlet fever, diphtheria, and other allied diseases are with or without spores. Of course, we don't know that there are any yet, for they have not been isolated, and it is, therefore, a question of doubt. Bacteriologists tell us that it is probable, by analogy, that these bacteria do not have spores. They are responsible for that statement. And, if this is the case, it seems to me that it is rash to abandon fumigation by sulphurous acid gas in the present state of our knowledge. I don't wish to be understood as arguing against the process of disinfection suggested by Dr. Harrington. This is a practical question. It is stated by sanitarians, and I think we have the figures to prove it, that secondary cases occurring after fumigation are very rare. I think that after small-pox in this city it is very rare.

DR. McCOLLUM: I have never heard of a case in the past eight years.

DR. PRINCE: If this is the fact, and if fumigation by sulphur is useless, then it seems to me the logical argument would be that the danger from the infection of an apartment is very slight, and nothing in the way of disinfection is necessary at all.

DR. McCOLLUM: I have nothing to say, Mr. Chairman; I think the ground has been very fully covered. I can only say that it is a rather remarkable fact that during the past ten years, at the Suffolk County Jail,

where we have three or four thousand patients in the course of the year, we have never had a case of typhoid fever originating in the jail. We have had, I think, cases which have been removed after a longer or shorter time, but it is rather a remarkable fact, where the inmates are placed in very close proximity, that a case has not originated. I think that is due to the manner in which the night-soil is disposed of. Every man has a bucket, that is washed every morning with chloride of lime. There are no drains.

In regard to the subject of fumigation, I would say, five or six years ago, we, unfortunately, had two cases of small-pox in the jail. Of course, as soon as the disease was recognized, the patients were removed and the cell was fumigated, as well as the blankets and everything that was used by the patients. No case arose from that, and, as I just told Dr. Prince, for the past five or six years there has never been a secondary case in the city unless it was contracted before the removal of the patient. Of course, it is impossible to say that this is due to the use of the sulphur, but I think it is very suggestive, to say the least. In scarlet fever, it is comparatively rarely that the place is fumigated a second time. It is not an uncommon thing for a child to be taken sick with scarlet fever, and then for another child to come down afterward, because the child contracted the disease before the removal. But after the house has been fumigated, it is very rare to have any patient come down after three or four weeks. Of course, that does not absolutely prove anything, but I think it does have an important bearing upon the question. Sulphur is comparatively an easy thing to use, and if it is entirely useless we want to know it. It seems to me that it does a certain amount of good. Of course, it is not perfect; there is nothing perfect. At the same time, it seems to me, in following up the course of scarlet fever for the last five or six years, you must be struck with the fact that the cases don't occur in the same houses. They are not contracted from the walls that have been fumigated or disinfected.

DR. FOLSOM: Several years ago, there was quite an epidemic of diphtheria in the lower ward of the Danvers Insane Asylum; that is to say, the ward in which the paralytic and demented patients were, and where there was a great deal of involuntary defecation of urine and feces, where it was impossible to keep the air entirely sweet. It could not be done. The case was clearly brought in from the outside, but it spread, and there was quite an epidemic. The first thing that was done was to use sulphur very thoroughly, and it was used with such careful medical supervision that I am convinced that it could not have been done more efficaciously. The patients were allowed to go back again, and there was another case. Then chlorine was tried just as efficiently as the sulphurous acid gas. The patients went back, and diphtheria again prevailed. Then the whole ward was cleared out and thoroughly disinfected in the way that Dr. Harrington has suggested, and there has never been any diphtheria there since. My impression is that that represents the theoretical and practical view of the question at the present time, but when we go so far as to throw aside the experiments which were made by Pettenkofer and his associates, and say that fumigation with sulphur does no good at all, it seems to me that we are going entirely too far. I don't see how any one can follow the results of the use of sulphur in any large city for a series of years and say that it

does not do some good. That the sulphur fumigation is not altogether and always efficient, I am convinced; and I think that practical and theoretical tests prove that beyond question. But here is a city with a dense population, and you must do something. It is not always possible to keep people out of their rooms, and in order to carry out the methods suggested by Dr. Harrington, you must often get the family out altogether. My own opinion is that the city of Boston ought to furnish efficient disinfection, and that families ought in some cases to be taken out of their houses, at least in diphtheria and scarlet fever. Public disinfection has been done in England for fifteen years, a fact to which I called attention in one of the State Board of Health reports nearly or quite ten years ago, giving also a full description, with plates and plans, of the public disinfection building in Liverpool, and of the public laundries in that city. In Glasgow, for the last four or five years, they have been taking families out from their houses, having houses for temporary residence for that purpose. The home is then gone through with by the method suggested by Dr. Harrington, and the family returns to it. It seems to me that there is no doubt but that is the only efficient way; the only question is whether the city or State is justified in undergoing such an expense, and whether the return is sufficient. It seems to me that the statistics of Glasgow show that it has been a profitable thing for the city to do.

DR. FITZ: I am very much obliged to Dr. Folsom and Dr. Rowe for the evidence they have brought forward in connection with the cases that I have presented. The degree of probability of transmission is relative. It presents itself more or less strongly in different cases. With a considerable degree of relative probability, it is, of course, important to take measures which shall tend to diminish the number of probable cases, and if cases occur, to make them rather possible than probable. The precautions which Dr. Rowe has shown to have been taken at the City Hospital are very much like those that have been taken at the Massachusetts General Hospital, and yet, the latter were apparently inefficient. How far the new directions are likely to be useful in the future, will have to be decided in the future, provided they are adhered to. Certainly, the precautions which are suggested in the paper I have presented are more specific than those which have hitherto been followed.

In regard to the question which has raised so much interest, of sulphur-fumigation in general, the evidence which I have followed has left me in a frame of mind which is very distinctly in favor of recommending the disuse of sulphur as a disinfectant. It is not so much that certain organisms are destroyed, as it is that certain other organisms are not destroyed by sulphur-fumigations; and since we have to deal with an unknown series of poisons, it is rather preferable to give up an agent which we know will not destroy certain organisms than to adhere to it and run the risk, perhaps, of neglecting means which may prove more efficient.

DR. CHARLES HARRINGTON: As to the value of sulphur fumigations, it is true, as Dr. Durgin has said and Dr. Prince, too, that the authorities whose work I have cited, showed that under some circumstances sulphur fumes do kill micro-organisms without spores. I did not consider it necessary in a paper such as mine to go into the particulars of the experiments of the

authorities cited. I have thought it quite sufficient to quote their conclusions. They all showed that micro-organisms without spores may, under most favorable conditions not likely to be obtained in actual practice, be killed by sulphur, but they also showed that under no conditions are spores affected. For this reason sulphur fumigations have been condemned as thoroughly unreliable, and my authorities unqualifiedly recommend the abandonment of the process. It is true, as Dr. Durgin has said, that Vallin, in his work on disinfection published in 1882, speaks a good word for sulphur fumigations, but it is equally true that in a more recent publication he endorses Koch's work and recommends steam. And it is true that Sternberg, as Drs. Durgin and Prince have said, proved the effectiveness of sulphur fumigations against certain micro-organisms, but it is equally true that in his Lomb prize essay he virtually concedes that sulphur fumigations are not reliable, though on a later page he says that many physicians think it advisable to use sulphur before proceeding to any other method. The fact that Sternberg has stated that there is good reason to suppose that certain germs do not form spores is not a sound argument in favor of sulphur fumigations. It is acknowledged by all that we know nothing about most of the germs mentioned, and it is, therefore, unsafe to recommend for their destruction a process which is admitted to have no effect on spores, on the mere supposition that they do not form them. Sternberg, himself, says that these germs have not been demonstrated, and also says that in practical disinfection in those cases in which the exact nature of the germ is not known, it is always best to employ a process which will kill spores. This, it seems to me, is equivalent to saying that sulphur fumigations are not to be relied upon in these diseases. If the Boston Board of Health do not, as Dr. Durgin says, claim that the sulphur process will kill the spore-bearing germ, and do not use it for that purpose, why use it at all in those diseases in which the formation of spores is doubtful or unknown, and in these diseases why not use a process which is known to be effective? I am obliged to disagree with Dr. Durgin as to the best means of disinfecting ships, for the results of the researches of Koch and Gaffky on this very subject are very conclusive—so conclusive that their recommendations have been adopted by the German naval authorities. The carting of infected material, which Dr. Durgin considers clumsy and dangerous, has been for some years carried on in many European cities, and, so far as I am aware, has been most satisfactory in its results. In Glasgow, the process of carting infected material to a public wash-house has been in vogue probably longer than elsewhere, in fact more than ten years, and during that time not a single case of interchanged disease has occurred. As to the objections urged by Dr. Durgin against rubbing walls with bread, it may be said that the same objections hold against sulphur fumes, for it has been abundantly proven that the gas does not enter cracks in all instances, for it does not diffuse itself well. It seems to me that the process of rubbing walls with bread has already been shown to be valuable. I cannot agree with Dr. Durgin that it is not likely to attract serious attention, for it has already attracted the serious attention of the German government and of many sanitarians.

Dr. Prince has remarked that sanitarians say that

secondary cases are very rare after fumigations. That may be, but at the same time there are enough cases published to show that they do occur frequently. I have recently read an account of a series of outbreaks of diphtheria in a military hospital in St. Petersburg. The ward was frequently fumigated and left vacant for weeks, and diphtheria would again break out as often as it was occupied. Finally, when both sulphur and chlorine fumigations were abandoned, and the process of disinfection by washing with carbolic or corrosive sublimate solution adopted, the diphtheria outbreaks ceased. Dr. Folsom has this evening related a similar experience.

Of course it cannot be said that sulphurous acid gas is *absolutely* valueless as a disinfectant, but in view of the fact that all leading scientists say that it is *practically* valueless and *thoroughly unreliable*, I think it is better to abandon it altogether, and adopt a process which we know to be reliable.

(To be continued.)

AMERICAN MEDICAL ASSOCIATION.¹

CINCINNATI, OHIO.

SECTION OF PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

FIRST DAY — TUESDAY, MAY 8TH.

Dr. N. S. Davis, of Chicago, opened the meeting of the above Section by announcing the death of Dr. A. P. Palmer, of Ann Arbor, the Chairman-elect, and the unavoidable absence of the Secretary, Dr. N. S. Davis, Jr., of Chicago.

Election of officers was stated to be in order, and was held with the following result: Chairman, Dr. W. C. Van Bibber, of Baltimore; Secretary, Dr. G. A. Fackler, of Cincinnati.

The first subject for discussion was

PNEUMONIA: ETIOLOGY, PATHOLOGY, AND TREATMENT.

Dr. VAN BIBBER, of Baltimore, opened the discussion with a consideration of the mechanism of pneumonia and its treatment. Dr. Van Bibber's paper had two objects: first, an inquiry into the initial causes of pneumonia; and, second, the treatment of the disease. He said a few words in regard to the anatomical arrangements of the parts. By the term mechanism of pneumonia, the author attempted to show, in a general way, how different changes in the structure of the lungs are brought about, which are recognized during life, are seen after death by the microscope, and demonstrated by the scalpel.

He recognized among the predisposing causes of pneumonia four, which are quite different from each other, and each one of which must produce the same effect — congestion in the capillaries — by a different mode of action. They are age, cold, malaria, and alcohol.

He arrives at the following conclusion: The predisposing causes, as the name implies, do not produce pneumonia *de ipso facto*, but they have already worked such structural changes in the body, that upon further disturbance of the system a congestion

of the numerous pulmonary capillaries is more likely to occur than any other diseased condition.

A study of the structural changes brought about by the predisposing causes give advantages in advisory prophylaxis, as well as in treatment. The author introduced the discussion of the treatment of pneumonia with the statement from Fothergill that: "Every new remedy, almost, is tried in turn for pneumonia. It is a disease particularly suitable to speculative medicine." He had determined to present the subject by means of four hypothetical cases: One a child of eighteen months; one a youth of twenty-five years; one case sixty years of age, complicated with malaria; and one case seventy years old, complicated with old age, malaria, and alcohol. In the discussion of these cases, much stress is laid on cupping over the roots of the lungs, between the shoulders, or more particularly still, between the third and eighth dorsal vertebra, in order that by the laws of counter-irritation over affected parts, the circulation through the roots of the lungs may be kept entirely free and open. It is also a means of controlling, or, at least, of moderating the effects of high arterial action during fever. It is valuable from the relief of pain and oppression it affords.

The medicines recommended are only five in number: Muriate and carbonate of ammonium, the former acting upon the circulation in the capillaries, assisting to unload them when they become engorged, as a resolvent, a general expectorant, and a diaphoretic; the latter as a stimulant, a resolvent, as a remedy which prevents the coagulating or engorging of blood in the capillaries. It may also be used as a vehicle in inhalations. Antipyrine and antifebrin serve to control the fever, diminishing the heat of the blood. Digitalis, veratrum viride, strychnia, strophanthus, and other remedies are valuable remedies in the hands of those accustomed to their use. In regard to the mechanism of heart-failure, Dr. Van Bibber remarked: First, there is diminished lung area, hence diminished supply of arterial blood; second, exudation and engorgement in the lung; third, the amount of blood which arrives in the heart to be forced through the obstruction. This brings a heavy weight upon the left ventricle. If this is continued, the heart must fail.

DISCUSSION.

Dr. WHITTAKER remarked that he did not exaggerate if he stated that the last two years had been more eventful in the study of pneumonia than any period in the two thousand years preceding them, for they removed it from the general to the acute infectious diseases. All the errors that cling to the disease have fallen. It does not attack the vigorous and strong, but shows a predilection for the feeble. Cold is no longer considered a cause of pneumonia. Juergensen was the first to show where the disease belongs, even without a definite knowledge of the cause. The speaker then recited the discovery of various microorganisms of pneumonia, selecting, finally, those of Friedländer and Fraenkel as the probable causative agents. We know that it may also be produced by other microorganisms, as by the typhoid bacillus or the staphylococcus of pus. There is, hence, no poverty of material. May there not, then, be many forms of pneumonia? One has been isolated and called croupous pneumonia; but may not this be divisible into a number of kinds? Thus far it has been divided into primary and secondary pneumonia,

¹ Continued from page 506.

the latter due to the invasion of the respective bacilli. Investigation has shown that in seventy to ninety per cent. of cases of true croupous pneumonia the bacterium of Fraenkel, the diplococcus, is found. The physician is thus enabled to diagnose pneumonia by means of the bacterium twenty-four hours before the manifestations of physical signs. The speaker described the process of staining. In this study we get some nice points as to treatment. The bacteria are sensitive to heat.

170°	attenuates the bacteria of Fraenkel in 24 to 48 hours.
105°	" " " " " 5 days.
104°	" " " " " 7 to 8 days.

This corresponds pretty well with the clinical history of a case of pneumonia. The fever may be the very agent destroying the disease. It has been observed that those were the most favorable cases in which the temperature was most pronounced. Danger is not from the fever, but from the heart, and the question is, whether it is not the best plan of treatment to sustain the heart. Let the fever alone. Be content with small doses of antipyrine and antifebrin to do away with any evil effects of high temperature. For the heart, nothing is better than digitalis. If stimulation be necessary, nothing is better than nitroglycerine and black coffee and alcohol. Under such *régime*, the speaker had found during twenty years' practice the mortality of pneumonia reduced from twenty to ten per cent.

DR. N. S. DAVIS thought it a curious fact that the mortality in pneumonia of to-day is undoubtedly greater than that of forty-five years ago. If anything is established, this very fact has been by statistics gathered not in the hospitals only but among the city and country population of the United States, in private and in general practice. As to the question of cold, it has been indubitably demonstrated that the disease prevails more during the winter than during the summer months. He referred to the statements made by a prominent Canadian physician, in one of the early meetings of the Association of the Dominion, to the effect that during a practice of thirty years, he had adopted three plans of treatment. During the first of the three decades the treatment consisted of bloodletting. The second decade constituted the transition period from the bloodletting antiphlogistic treatment to the expectant plan. The third decade the stimulant method. He found in footing up his records, that the mortality was least during the first decade, and greatest during the last. The speaker dwelt at some length upon the benefits derived from bloodletting during the first stage, followed by cardiac depressants during subsequent twenty-four to thirty-six hours. He cited cases in illustration.

DR. VON KLEIN, of Dayton, O.: During service in the Russian army had found that pneumonia prevails to a less extent in a climate in which the temperature averaged 50° below zero, than in our moderate climate. He believed in the judicious use of the lancet. He ascribed the increasing mortality to the fact that the people are not as robust as those of fifty years ago. They have changed as to their surroundings, habits, clothing, etc., and our treatment ought to be guided by the peculiarities of each case.

DR. OCTERLONY, of Louisville, took issue with Dr. Davis in regard to increased mortality. During the time of bloodletting, the mortality was one in five. During the time of mixed treatment, according to the

statements of Skoda and Austin Flint, the results improved fifty per cent. J. H. Bennett, of Edinburgh, introduced the method of furthering the natural progress of the disease with the result that the mortality was reduced to one in thirty-six. The speaker had on former occasions defended the theory that pneumonia depended upon local causes, that the changes were local and that they were amenable to local treatment. But impelled by more extended observations, he had become a convert to the theory of pneumonia being an essential specific fever due to a specific cause, probably the pneumococcus. He thought that a physician was rarely called to a patient during the first stage, but generally when the exudation had already commenced.

DR. JENKINS, of Iowa, attributed the apparent increase in mortality to the improved facilities in diagnosis and the advances in our knowledge in pathology.

DR. BAILY, of Louisville, advocated decidedly the use of stimulants, especially during the last stage.

DR. F. C. SHATTUCK, of Boston, protested against the use of internal antipyretics as advocated by the reader. We have all of late years attached too much importance to the effects of temperature in febrile affections. The pyretic stage of pneumonia is usually short and the danger of serious or fatal collapse following crisis heightened by the class of drugs of which antifebrin may be taken as the representative.

DR. VAN BIEBER, in conclusion, stated that he had received a letter from Dr. W. H. Welch, in which the statement was made that "it is apparent that the evidence is not conclusive that either of the organisms named is the infectious agent of croupous pneumonia, certainly no such evidence has been presented as that which leads us to accept the tubercle bacillus, the typhoid bacillus, or the cholera spirillum as the cause of their respective diseases."

DR. FRANK WOODBURY, of Philadelphia, spoke of the

HIPPOCRATIC OPERATION FOR EMPYEMA, and reported a case in illustration of his subject.

DR. MORRIS H. HENRY, of New York, in a paper entitled

MY OWN CLINICAL EXPERIENCE IN THE ADMINISTRATION OF THE IODIDE OF POTASSIUM IN THE TREATMENT OF SYPHILIS,

prefaces his remarks with a few words on the value of mercury in the early, and what is termed the middle, period of the evolution of the disease. In the discussion of the subject proper, the essayist stated that the dose of the iodide may vary from five to fifty grains every four hours: from thirty to three hundred grains in every twenty-four hours. He spoke of the value of the remedy in syphilitic rheumatism. The remainder of the paper dwelt upon the claims of various authors to the priority of the adoption of the treatment of late and inveterate lesions of syphilis by the administration of large doses of iodide of potassium.

SURGICAL SECTION.

FIRST DAY, TUESDAY, MAY 8TH.

DONALD MCLEAN, M.D., Detroit, Chairman; B. A. WATSON, M.D., Jersey City, N. J., Secretary.

Address by the Chairman:

SOME THOUGHTS ON RETROSPECTIVE AND PROSPECTIVE SURGERY.

In alluding to the great improvements that have

been made in the operation of ovariectomy, the Chairman observed that Lawson Tait, as well as other eminent surgeons, has discontinued the use of the so-called antiseptics, and has denounced them as delusions and snares. Too much importance is attached to certain fashionable antiseptics, and too little to the far more reliable antiseptic measures of general cleanliness and healthy surroundings. At a matter of abstract and scientific truth, the doctrines of Lister have done much to advance the science of medicine; and whatever may be the fate of the germ theory, anything like a return to the old, loose methods of surgery will be impossible.

He believes that chloroform properly and judiciously used is the safest and most efficient general anæsthetic we possess; and a successful experience of thirty years of its use, in which time no accident has occurred in his hands, has confirmed him in this belief.

In reference to the progress made in surgery by aid of the microscope, he does not think that the results have been as great as was expected by its advocates, and, as a means of diagnosis, it surely has not superseded the old precepts which are the results of many years of clinical experience.

The field for the application of electricity in surgery is as yet quite limited. That by electrolysis, certain cases of stricture of the urethra may be alleviated, and even cured, there can be no reasonable doubt; but that this means of operation would ever produce as satisfactory and complete results as are obtained by urethrotomy, either external or internal, he could not believe. The application of electrolysis in fibroid tumors of the uterus, according to the method of Keith, has undoubtedly proven of benefit. The value of electrolysis in the treatment of navus is a triumph of surgery belonging to America.

The introduction of the Esmarch bandage and catgut ligature, and the abandonment of styptic remedies, except in certain well-defined cases, mark an era in our surgical history. He found that an animal ligature was thoroughly efficient in a case of ligation of the femoral just below Poupert's ligament, and also in a case where the popliteal artery was tied; and in most cases it will be found to be all that is required of it.

The treatment of diseased joints has made very satisfactory progress. Resection, especially of the hip and knee, has a very much larger field of use than has formerly been conceded. To remove all the diseased tissue in a case of tubercular disease of the knee-joint is almost an imperative practice.

In the treatment of fractures, the improved and simplified methods for procuring extension, especially in fractures of the femur, have gained almost unanimous indorsement. He believes that the use of plaster-of-Paris in these cases is limited.

The use of splints in the treatment of Colles's fracture is not necessary, and by leaving them off we can better attend to passive motion, which is so essential in all fractures near joints to prevent ankylosis.

As to stone in the bladder, there are substantial advantages in the classical operation of lithotomy that will always make it superior in many cases to those of lithotripsy or litholopaxy. After lithotomy, proper drainage, which is so essential in many of these cases, can be secured; and this reason makes the lateral operation superior to the supra-pubic, except in special cases.

THE APPENDIX VERMIFORMIS: ITS FUNCTIONS, PATHOLOGICAL CHANGES, AND TREATMENT,

by HENRY HOLLINGSWORTH SMITH, of Philadelphia.

Special Anatomy. This organ is about the size of a goose-quill. In cases of extreme length (6 or 8 inches), its free end may become wound around the small intestine, and form a constricting band. At its opening, which is not at the most dependent portion of the cæcum, but on its posterior wall, there is a ridge of mucous membrane which acts as a valve to prevent the contents of the cæcum from escaping into the cavity of the appendix. He contends that this valve-like arrangement will withstand considerable pressure, and for this reason the danger of seeds and other foreign bodies getting into the appendix is not so great as has been thought. When the opening becomes occluded from any cause, this organ may undergo distension by its own secretion and form mucocele. In the fœtus, it is frequently found filled with meconium.

The use of this organ is undetermined, but it is not intended for a cherry-seed trap. Any speculations as to its use seem to be mere hypotheses. Tiedman and Mellin observed that the juice of the appendix has a slight digestive power.

One of the earliest symptoms of inflammation of this organ is constipation; and as an inflammation here leads to constriction, obstruction, and distension of the duct, and finally, abscess and peritonitis, we should use such remedies to promote peristalsis as will assist to empty it.

Specks of hardened feces and small concretions composed of calcium, magnesium, and phosphoric acid, which are often mistaken for foreign bodies, are frequently found in this organ. Pyæmic abscesses, peritonitis, perinephritis, and empyæmic abscess have all been reported as results of appendicitis.

Owing to the obscurity of symptoms, and the similarity of them to other intestinal lesions, the diagnosis is not easily made, and in some cases is only arrived at by exclusion.

The treatment should embrace the use of calomel and saline purgatives, enemata containing turpentine, opiates to relieve pain. Palpation, under ether, may be tried, in an endeavor to favor peristalsis. When the symptoms of abscess appear, and the temperature becomes elevated, operative procedure is justified, but the use of the remedies enumerated should precede laparotomy. The symptoms of perforation at any time would, of course, indicate operative interference. After cutting down upon the cæcum, the appendix should be carefully examined for calculus before anything else is done, and if a concretion, or a perforation, or a distension indicating an obstruction be found, the duct should be ligated near the cæcum and removed.

DR. J. McF. GASTON, Atlanta, Ga.: In alluding to the effectiveness of the valve-like arrangement at the mouth of the appendix vermiformis, stated that in certain cases the cæcum had been found distended and even ruptured, while the appendix remained collapsed. It is rare to find any indication of trouble here before actual inflammation, suppuration and abscess occur.

A digital examination per rectum may enable the surgeon to detect the presence of an abscess in the iliac region. Perforation forms a dividing line in the symptom; before this, the diagnosis is doubtful, after

it has occurred, it is plain. As to treatment, he regards a masterly inactivity as more prudent than aggressive interference. Anodyne and soothing applications are always in order. Exploratory incision is advisable when there is strong evidence of disease; the incision can be closed and no harm may be done. When it is certain that appendicitis exists, the operation cannot greatly augment the danger to life, and may result in a cure. He thinks that through an incision made to the outer side of the rectus muscle, an appendicular extravasation can be more readily treated.

DISCUSSION.

DR. T. G. MORTON, Philadelphia: In the vast majority of cases perityphlitis is caused by a concretion of phosphates of calcium and magnesium or of hardened faeces or else by some foreign body in the appendix. Whenever we have any evidence of an abscess in the iliac region we should always suspect this disease, and endeavor to expose the abscess. A simple emptying of the abscess cavity will not suffice, but it must be exposed to view and treated.

Among the earliest symptoms of appendicitis we find that severe pain of a paroxysmal character is one of the most prominent; constipation is present. Inflammation, nausea, vomiting, elevation of temperature and evidences of pus in the iliac region rapidly appear. Before pus can be actually detected by physical signs, its presence may be diagnosed by the general symptoms that indicate its existence at any point. Before the appearance of pus the iliac region is tympanitic. Perforation is ushered in suddenly by excruciating pain with nausea and vomiting.

The treatment should include operative measures as well as the palliative opiates, fomentations, etc., for the danger of operation becomes slight compared to the danger of abdominal inflammation, which is certain to occur if the case is left to nature.

The exploratory needle should never be used, for it does not furnish absolute evidence, and its use is not devoid of danger. The incision for the operation should be lateral and not in the median line, for the necessary manipulation can be more readily performed and subsequent drainage more easily secured through a lateral opening. He has learned by dissection that the appendix may be found under a horizontal line drawn from the anterior superior spinous process of the ilium to the median line. If a perforation of the cæcum should be present, it should be cleansed and closed with Lembert sutures. If the cause of the perityphlitis lies in the appendix, it should be ligated close to the cæcum and removed. The abscess-cavity should be thoroughly irrigated, a glass drainage-tube introduced and a dry antiseptic dressing employed. In most cases he does not close the opening but allows it to granulate; the cæcum which is firmly fixed in its position cannot escape.

In summarizing his remarks he dwelt upon the opinion that it is far better to operate than to wait, for the prognosis grows more serious every hour the operation is postponed. The secretions should be washed away through the glass drainage-tube as often as the temperature and odor indicate.

(To be continued.)

— Don't write your prescriptions for solanin on too liberal a scale. It costs two dollars a gramme.

THE BOSTON Medical and Surgical Journal.

THURSDAY, MAY 24, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

EMBRYOCARDIA. — THE LOWERED ARTERIAL TENSION IN TYPHOID FEVER. — THERAPEUTIC INDICATIONS.

THERE is a cardiac symptom to which Huchard calls attention in a recent lecture in Bichat Hospital, and to which he attaches a great prognostic importance. It is the *fætal* character of the sounds of the heart, which consists of the perfect equality, as to duration, of the greater and lesser pause. The heart sounds are, therefore, equal and precipitate, and have a striking resemblance to the ticking of a watch and the beatings of the fetal heart. Huchard gives to this quality of cardiac action the name of *embryocardia*, and regards it as a symptom of the very worst augury. It is always associated with *tachycardia* (acceleration of the pulsations), and is a sign, not only of enfeeblement of the heart, but also of a considerable fall in the arterial tension, two inseparable conditions of the collapse which often attends the later periods of typhoid fever.

Huchard relates the particulars of a case to which he was called in consultation. The patient was a young girl, fourteen years of age, and it was the eighth day of the fever. The disease was seemingly progressing with all the regularity desirable: the rose spots were beginning to show themselves; the diarrhoea was moderate, and not fetid; the tongue was moist, and the cerebral condition satisfactory; the lungs and bronchi were intact, but there was a febrile temperature of 104° F. Notwithstanding this febrile elevation, the medical attendants were disposed to give a favorable prognosis, when Huchard called their attention to the rapidity of the pulse (130 per minute), and the fetal character of the heart sounds, and announced the certain and near death of the patient, which took place within two days.

In another case, in many respects similar to the above, Huchard thinks that he saved the life of the patient by a kind of treatment which he earnestly recommends in threatened collapse, and which consists in hypodermic injections three or four times a day, of caffeine and ergotin. The formula is fifteen grains of

ergotine and four grains of caffein, dissolved in some suitable menstruum, and injected subcutaneously. Whenever, then, the foetal character of the heart sounds is perceived, this injection is, he believes, indicated. Nor would he be deterred by a cyanotic appearance of the integuments and coldness of the extremities.

In 1886 Demange published in the *Revue de Médecine* a very striking case in favor of treatment similar to that above pointed out. He mentions the same quality of the heart sounds, "whose rhythm resembled the foetal rhythm." The patient was a young girl eleven years of age, suffering from grave typhoid fever of ataxic form. She was taken with repeated attacks of syncope. The pulse was small and compressible, oscillating between 140 and 150. The extremities were cold and cyanosed, the heart sounds feeble and precipitate. The respiration at times was of the Cheyne-Stokes kind, and death seemed imminent. Under the influence of three injections of one gramme of ergotine (associated with subcutaneous injections of ether and digitalis by mouth) the pulse improved, the symptoms of syncope vanished, and the patient eventually recovered.

Bernheim (quoted by Huchard) who has written so much upon a certain *cardiac form* of typhoid fever, attributes these morbid accidents to the action of the typhoid poison on the vagus and on the cardiac innervation. He thinks that this poison acts after the manner of digitalis and the biliary acids which slow the heart by irritation of its moderator centre. This it is that explains the relative slowness of the pulse in dothinenitis. But just as digitalis in toxic dose causes acceleration of the pulse, so also the typhoid poison when in excess in the blood, may produce paralytic acceleration of the heart. This theory seems confirmed by the results of the administration of therapeutic agents. Often, in fact, digitalis when given in this cardiac form of typhoid fever, seems to do more harm than good, by adding, as it were, its effects to those of the typhoid poison.

But this is not all. Besides the nervous and other lesions of the myocardium in typhoid fever, there are certain arterial lesions, whose existence was demonstrated in 1869 by Hayem, afterwards by Landonzy and Siredey, and of all diseases, says Huchard, typhoid fever is the ofttest accompanied by marked diminution of the vascular pressure. Potain has demonstrated this lessening of arterial tension in dothinenitis by means of the sphygmomanometre. Thus he has seen the pressure fall to fourteen, and even to eight and seven centimetres, the normal being represented by sixteen and eighteen centimetres. This enfleebment of the arterial tension is also indicated by the diastolic sound of the aorta, and by the acceleration and foetal rhythm of the heart.

In explaining the production of this latter phenomena, the "embryocardia," Huchard hypotheates a

direct action of the fever poison on the peripheral arterial contractility, which is impaired or destroyed thereby. The heart, then, according to a law of Marey, beats the faster the less the peripheral resistance it has to overcome. Moreover, its moderator nerve being paralyzed, it readily runs riot. Symptoms of asphyxia and cyanosis show themselves the more speedily the more the heart muscle becomes soft and fattily degenerated.

The danger, then, is with both the heart and peripheral circulation. The caffein is administered with the intent to fortify the heart, while it is sought to combat the condition of the arteries by ergot of rye, which raises arterial tension, and augments the contractility of the vessels lessened by the typhoid poison.

Moreover, the hypodermic method is preferred for the reason that the ergotin and caffein are thus more readily introduced into the blood. In fact, in typhoid fever the power of absorption by the digestive tube is low, by reason of the profound lesions which affect the intestine, as is demonstrated by the large doses of quinine (three to five grammes) which are often given with impunity in this disease.

BLOOMINGDALE ASYLUM TO BE REMOVED.

THE Society of the New York Hospital has now determined upon the removal of the Bloomingdale Insane Asylum to White Plains, where it already owns a tract of land suitable for such an institution. It is 117 years since the Society was chartered, and over 72 years since it purchased, for \$4,000, the site at present occupied by its asylum; and the buildings were opened for the reception of patients, July 27, 1821.

The grounds extend from 110th to 114th Streets, and from 10th Avenue to the Boulevard, comprising 558 building lots, which are now valued at from \$5,000 to \$8,000 each. This piece of property, situated, as it is, on the high and picturesque land between Morning-side and Riverside Parks, is one of the finest for residence purposes on Manhattan Island, and the decision of the Board of Governors to remove the institution to a greater distance from the city is no doubt a wise one. The buildings will all be demolished, with the exception of the John C. Green Memorial Building, a very substantial and handsome brownstone structure, which will be allowed to remain, and will be converted by the Society into a general emergency hospital.

No formal action has been taken as to the disposal of the property, but it is understood that as soon as the new buildings at White Plains are ready for occupancy, it will be properly subdivided and put up at auction for the sale of the lease-holds only. These lease-holds, it is supposed, will produce an income of nearly \$200,000 a year. At the recent meeting of the Board of Governors at which the removal was decided upon, it was determined that \$1,000,000 should be appropriated for the building of the new asylum,

that plans and specifications be prepared, and that the work be entered upon without unnecessary delay.

In furtherance of these objects, committees were appointed to devise a financial scheme to provide the necessary funds, and to secure suitable plans for the proposed buildings. Before the removal was finally determined upon, a favorable report was received from a Commission of sanitary experts which had been appointed to investigate the suitability of the White Plains property for the purpose contemplated.

THE SUPERIORITY OF ANTIFEBRINE OVER THE ANTIPYRETICS.

BERNHEIM and Simon, of the Faculty of Nancy, have communicated to the *Revue Médicale de l'Est*, the results of their experiments with antifebrine. They have studied it solely from the point of view of its antithermic action. The daily doses varied between four and thirty grains. The ordinary antithermic dose for an adult is from three to five grains, which may safely be repeated every hour until a sufficient fever-fall is produced. According to their observations shortly after the ingestion of the medicament the temperature begins to fall, and at the end of four hours the minimum thermic point is reached; the temperature then begins to rise, and at the end of three or four hours it has regained its initial degree. These clinical observers have deduced from their experiments the following conclusions: Antifebrine is not alone an analgesic, as has been said, but it is a true antithermic medicament, efficacious, and without danger, (they have, in fact, seen no bad results in two hundred and twenty-three cases in which they have fairly tested it). Its antipyretic action does not manifest itself by any marked sign, and the thermometric fall does not result from a modification pure and simple in the distribution of the organic temperature.

If, in fact, you study the variations of the rectal temperature and of the peripheral temperatures under antifebrine, you see that the thermic fall is produced at the same time in different points of the cutaneous surface, while the central temperature diminishes contemporaneously.

Antifebrine is much superior to all the other antithermics known, and to antipyrine in particular; it has over the latter the advantage of a composition that never in the least varies, is of moderate price, and is perfectly tolerated by the digestive passages. Lastly, its greater activity enables us to employ it in doses four times less than antipyrine.

THE BOSTON SEASHORE HOME.

The twelfth annual report of the Boston Seashore Home for the summer of 1887, just published, shows, according to the report of the visiting physician, Dr. C. W. Townsend, that the whole number of inmates between July 1st and September 15th was 317, and of

these 199 were children, 117 of them being under three years of age.

The diseases treated were largely diarrhœal — 87 cases — divided into cholera infantum — 7 cases — of which 2 recovered and 5 died; gastro-intestinal catarrh, 20 cases, of which 10 recovered, 5 were relieved, 4 not relieved, and 1 died; and intestinal catarrh, 60 cases, of which 46 recovered, 11 were relieved, and three not relieved. Three infants died from tuberculosis in some form, one from lobular pneumonia, and one from lobar pneumonia. Two of the cases of cholera infantum were moribund on arrival, and all the deaths occurred in hand-fed infants.

The old building was crowded to its utmost capacity during July and August, and the need of new and enlarged quarters is earnestly urged in the report by Edw. E. Hale, one of the directors, who appeals for \$10,000 for this purpose. The Home is at Winthrop, a short distance from Boston on the Revere Beach Railroad, and receives sick infants and young children with their mothers during the hot weather. Applications may be made to Dr. Hastings or to the visiting physician.

MEDICAL NOTES.

— Sir Morell Mackenzie's compensation for attendance on the Emperor Frederick is said to have been fixed at \$15,000 per quarter (three months), or any portion of that time. This seems like a liberal fee, but it is to be remembered that the proceeds of his private practice in London are reported to be \$75,000 per annum.

— The *Druggists' Circular and Chemical Gazette* for May publishes two very amusing "parallel column" portraits, the one purporting to be a medical man, the discoverer of a certain widely advertised proprietary medicine, and the other being actually a portrait of Ludwig Spohr, the composer, who died in 1859. The pictures are liker than the two Dromios; in fact, are evidently identical, even to the last curl of the hair and the fold of the cravat. The inference is, therefore, very naturally drawn that the eminent medical discoverer referred to by the advertisers has no existence, and he is thus relegated to the same limbo with the late lamented "Mrs. Harris."

— The danger of infection from the use of books from circulating libraries has received intelligent attention in England, says *Science*, and means have been devised for their disinfection. The principle on which disinfection is based is the vaporization of carbolic acid by heat, whereby it is claimed that its action is more potent. Heat is applied to the outer casing of an apparatus, which is fully under control, so that a temperature which might injure the books can be avoided. The heat employed is from 150° to 200° F., the books being subjected to this temperature for fifteen minutes, and not injured by the process. The apparatus is said to be patented. Whether the process is applied to all books each time they return to the

library, is not stated. But unless this is done, it does not seem that there is any security from disinfection, for no one can tell whether, in a given instance, the book has received infection or not.

— There is one of the high schools not ten thousand miles away where physiology is a required study. Recently a lady came to the principal with a request that her daughter might be excused from that study. The principal explained to her that the study was required, and that a diploma could not be given unless the examination in that study were passed, or unless some satisfactory excuse were furnished. After some hesitation the mother gave as her reason for objecting to the study that she intended her daughter to study Christian Science after leaving school, and she believed that a previous study of physiology would be injurious to her. She was probably right.

BOSTON.

— The Oleomargarine Bill, which passed the lower house and was advanced to the third reading in the Senate, failed of engrossment last week, the President of the Senate voting in the negative to break a tie. This week, the matter coming up again on motion to reconsider, that officer again voted in the negative, his vote this time making a tie, so that reconsideration failed, and the measure is defeated.

NEW YORK.

— The Legislature, before its adjournment, passed an act, which received the approval of the Governor, appropriating the sum of \$250,000 for expenditures in connection with Quarantine. These expenditures are to be made through the hands of a Commission consisting, in accordance with the provisions of the act, of the Mayors of New York and Brooklyn, the Health Officer of the Port of New York, the State Engineer and Surveyor, and the Commissioners of Quarantine; and among the items contemplated are the following: \$50,000 for care, maintenance, and repair of the Quarantine establishment, \$121,000 for repairs at Hoffman Island and the upper boarding-station, and \$25,000 for a new hospital-ship.

— Governor Hill has issued a proclamation establishing a cattle quarantine in the counties of New York, Kings, Queens, Richmond, and a portion of Westchester, on account of the prevalence of pleuropneumonia, and empowering Professor James Law, of Ithaca, to appoint such inspectors of the United States Bureau of Animal Industry as may be necessary for the suppression of the disease.

— A man who was recently bitten by a rattlesnake at Fort Lee (at the lower end of the Palisades) has had a narrow escape from death. He was treated at the Manhattan Hospital in Harlem, which is connected with Fort Lee by ferry, and is now out of danger; the principal agents employed being whiskey and carbonate of ammonia. It is a long time since any rattlesnakes have been met with as near the city as in this instance.

— It is announced from Nyack, on the Hudson, that nine of the lawyers of Rockland County have challenged the physicians of the county to play a game of base-ball. The communication concludes in the following considerate language: "Should you accept this challenge, we would suggest that you provide yourselves with an ambulance and an efficient surgeon to be in attendance upon you during the progress of the game, as we expect to paralyze you."

— At Westburg, near Brooklyn, a few days ago, were married a colored widower and widow at the venerable ages of 93 and 86.

— Dr. Howard Pinkney, a well-known New York practitioner, died very suddenly in England on the 14th of May. He had gone abroad for his health, and his death took place on a train from Southampton to London very shortly after he landed. Dr. Pinkney was born in New York in 1837, and graduated from the College of Physicians and Surgeons in 1860. After serving for some months on the house-staff of Bellevue Hospital, he entered the army at the outbreak of the late war as surgeon of the Ninth Regiment, New York Volunteers. He was in the field at the battles of Ball's Bluff, Harper's Ferry, Antietam, and South Mountain, and several times was assigned to special hospital duty; at one period having charge of the United States Army Hospital at Frederick City, Maryland. Since the war he has practised in New York City, devoting himself more particularly, though not exclusively, to diseases of the ear, to which subject he made many useful contributions in the medical journals. For twenty years he was surgeon to the New York Eye and Ear Infirmary, and for nine years was connected with the dispensary belonging to the Church of the Holy Trinity. He was a widower, and leaves one son, Dr. W. H. Pinkney, who has of late been associated with him in practice.

— Dr. Edward Hamilton Davis, who had a high reputation as an archæologist, died at his residence in Harlem, May 15th. He was born in Ross County, Ohio, January 22, 1811. He received his classical education at Kenyon College, and was graduated from the Cincinnati Medical College in 1838. He practised with great success as a physician at Chillicothe, Ohio, until 1850, when he came to New York to reside. Since that time he has devoted his attention mainly to archæological research, and he soon became an acknowledged authority on American antiquities, delivering courses of lectures on this subject in New York, Boston, Brooklyn, and other cities. He opened nearly two hundred mounds at his own expense, and gathered the largest collection of mound relics ever made in this country. It now forms part of the collection at Blackmore's Museum at Salisbury, England, and a duplicate collection is to be found at the American Museum of Natural History, New York. He describes his extensive explorations and their results in a work much prized by archæologists, entitled, "Ancient Monuments of the Mississippi Valley."

Correspondence.

MANY LIVING GENERATIONS.

LEAVENWORTH, KANSAS, May 12, 1888.

MR. EDITOR.—*Apropos* of the six and five living generations mentioned by Drs. Root and Channing, I would state that last month I attended a girl who was fourteen years old last December, in her first labor, the child being a healthy boy, his grandmother who was present was 28 years old and his great-grandmother was also present and but 49 years of age, making a shorter list of living generations than they mention, but a much younger great-grandmother.

Speaking of this to a friend at the table he informed me that at a recent reunion of his family there were present his sister's grandchild, 1 year old, his sister's daughter, 20 years old, his sister 40 years old, and his grandmother 94 years old. The chain was broken by the absence of his

father who died 20 years previously at the age of 40, but there was present an aunt nearly the same age who might serve as a substitute.

I would also mention, not as a remarkable fact, but as calling attention to frequent child-bearing as a fruitful source of debility in women, the cases of two women who happened to be in my office at the same time. One was married at the age 23, is now 40, and has had 9 children: of these, three were born on December 8, 1884, March 9, 1886, March 13, 1887. The other, now 43 years of age, has had 7 children: the dates of 4 of the births were February 4, 1867, March 13, 1868, December 27, 1869, March 19, 1871. The other children in both families were only slightly different in age, although the births were not quite so frequent. When families are brought into existence at such rates as these it is to be wondered at that so many mothers seek for some method of preventing conception?

W. D. BRIDWELL, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 12, 1888.

Deaths reported 2,058: under five years of age 794; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 340, acute lung diseases 324, consumption 208, diphtheria and croup 109, scarlet fever 17, diarrheal diseases 46, typhoid fever 45, measles 34, whooping-cough 21, cerebro-spinal meningitis 21, small-pox 9, erysipelas 9, malarial fever 6, puerperal fever 5. From typhoid fever, Philadelphia 29, New York three, Pittsburgh and Lowell two each, Boston, New Orleans, Milwaukee, Charleston, Worcester, Lawrence, and Taunton one each. From measles, New York 15, Baltimore eight, Pittsburgh four, District of Columbia three, Boston, Milwaukee, and Lowell one each. From whooping-cough, New York 10, Charleston four, Philadelphia three, New Orleans two, Baltimore and District of Columbia one each. From cerebro-spinal meningitis, New York three, District of Columbia, Pittsburgh, Milwaukee, and Lowell two each. From small-pox, New York five, Philadelphia four. From erysipelas, New York five, Cincinnati three, Boston one. From malarial fever, New York four, Philadelphia

and Baltimore one each. From puerperal fever, Milwaukee three, Philadelphia and Pittsburgh one each.

In the 20 cities and larger towns of Massachusetts, with an estimated population of 1,005,167, the total death-rate for the week was 19.61, against 23.43 and 20.87 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending April 28th, the death-rate was 18.9. Deaths reported 3,400: infants under one year of age 848; acute diseases of the respiratory organs 345, scarlet fever 48, measles 38, diphtheria 35, diarrheal diseases 34, fevers 25, small-pox (Sheffield five, London and Bristol one each) seven.

The death-rates ranged from 25.9 in Blackburn to 14.7 in Bolton; Birmingham 17.1; Bradford 19.5; Hull 14.7; Leeds 20.7; Leicester 23.5; Liverpool 21.3; London 17.5; Manchester 24.8; Newcastle-on-Tyne 16.1; Norwich 19.5; Nottingham 18.3; Sheffield 21.6; Sunderland 18.2; In Edinburgh 18.3; Glasgow 24.4; Dublin 31.5.

The meteorological record for the week ending May 12, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Baromet-	Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 12, 1888, TO MAY 18, 1888.

Paragraph 11, S. O. 104, A. G. O., May 5, is amended by Paragraph 4, S. O. 108, A. G. O., May 10, 1888, and Major Charles R. Greenleaf, Surgeon, Major Robert M. O'Reilly, Surgeon, and Captain John O. Skinner, Assistant Surgeon, are detailed as a board of medical officers to assemble at the United States Military Academy, West Point, N. Y., on June 1, 1888, to examine into the physical qualifications of the candidates for admission to the Academy, and, in connection with the superintendent of the Academy and commandant of cadets, the members of the graduating class.

APPEL, D. M., captain and assistant surgeon. Will be relieved from duty at Fort Davis upon the arrival of Capt. J. V. Lauderdale, assistant surgeon, and proceed to Fort Hancock, and report to the commanding officer of that post for duty. S. O. 49, Department of Texas, May 5, 1888, and S. O. 50, Department of Texas, May 9, 1888.

EDIE, GUY L., first lieutenant and assistant surgeon. Will proceed, not later than the 25th inst., to Fort Concho, and report to commanding officer, Eighth Cavalry, for duty as medical officer, in compliance with Paragraph 13, S. O. 99, c. s., Headquarters of the Army. S. O. 49, Department of Texas, May 5, 1888, and S. O. 50, Department of Texas, May 9, 1888.

WALKER, F. V., first lieutenant and assistant surgeon. Will be relieved from duty at Fort Ringgold, and proceed with Company D, 16th Infantry, to San Antonio; he will then report for duty to commanding officer, Post of San Antonio. S. O. 49, Department of Texas, May 5, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 19, 1888.

KERSHNER, EDWARD, surgeon. Detached from United States ship "Pensacola" and wait orders.

SAVIER, J. S., assistant surgeon. Detached from United States ship "Pensacola" and wait orders.

JONES, W. H., surgeon. Detached from Navy Yard, League Island and to "Pensacola."

COOKE, G. H., surgeon. Ordered to the Navy Yard, League Island.

CRAWFORD, MILLARD A., passed assistant surgeon. Ordered to the "Vandalia."

WIEBER, F. W. F., assistant surgeon. Detached from "Vandalia" and ordered home.

STONE, E. P., assistant surgeon. From Naval Hospital, New York, and to the "Pensacola."

HARMON, G. E. H., passed assistant surgeon. Commissioned a surgeon, May 12.

LECTURES. UNIVERSITY OF VERMONT.

T. D. Crothers, M.D., of Hartford, Conn., will deliver a course of lectures on the "Diseases of Inebriety, its Pathology and Treatment," at the Medical College of the University of Vermont, in Burlington, May 22, 23, and 24, 1888, at 10 A. M. each day.

OBITUARY. EDWARD SWIFT DUNSTER, M.D.

Edward Swift Dunster, M.D., of Ann Arbor, Michigan, professor of obstetrics and diseases of women and children in the University of Michigan, died on Thursday, the 3d inst., at the age of fifty-four years. Dr. Dunster was born in Maine, took his college course at Harvard, and obtained his medical education in New York. He served as a medical officer in the Army of the Potomac, and after the war practised in New York City. He taught in various capacities in Dartmouth College, the University of Vermont, and the Long Island College Hospital, and was appointed to his chair in the University of Michigan, in 1873.

DEATH.

Died, in Newburyport, Mass., May 17, 1888, Enoch Cross, M. D., M.M.S.S., aged eighty-six years.

BOOKS AND PAMPHLETS RECEIVED.

TWELVE YEARS IN THE DEVELOPMENT OF
A CASE OF MORAL IMBECILITY.¹

BY ALBERT N. BLODGETT, M.D., BOSTON, MASS.

PERHAPS I should preface the short paper which I have the honor to present, by something in the way of an apology, both for presuming to claim the attention of this Society by the narration of only a portion of a case, however so great the interest attaching to the subject itself may be, as well as for employing the term I have adopted in the title of the paper.²

I will only remark that this attempt to present what has been to me for some years a subject of great and increasing interest, is to be regarded only as a preliminary report which will probably be followed at some future time, by the sudden and unexpected development of additional and important symptoms, which I trust to have the pleasure of laying before you as a further chapter in the history of this case to which in all probability the possible autopsy of the patient may be added as the conclusion; and I venture to express the hope, the key to some of the features which have thus far proved to be of most serious importance.

The patient is a boy, born in Boston, or its near vicinity, where he has always lived, and whose career has ever been the object of much anxious solicitude on the part of dear and conscientious friends. He is at present fifteen years and seven months of age, as attested by his mother, his friends, and as recorded by his own hand within a short time. The importance of this varied evidence as to the age of our patient will become evident a little further on. As a child, this boy was the recipient of much attention, and showed at an early period, signs of great mental activity. He developed into a precocious child, and at three years was able to read, to recite, etc., all the usual phenomena of precocity being present. He was and is a strongly developed, large framed boy; the head is large, the hands broad, the limbs sturdy.

The antecedents of the patient are capable of accurate verification and in brief are as follows. The father of the boy was a man reared in a maritime town, of good stock, and who early became a sailor, and was the master of successive ships trading to the various commercial ports of the Indian Ocean, and making many voyages around the capes at the southern portions of the Eastern and Western continents. During one of these passages, the vessel was wrecked and the crew was exposed to great hardships, among which starvation and anthropophagy is supposed to have been included. On a subsequent voyage to the Indian Ocean, the captain was attacked by a peculiar disease, affecting the body and limbs something in the

way of acute diffused neuritis, with active delirium and permanent deterioration of the mental faculties, as was currently believed. The accounts of this malady are somewhat meagre, being gleaned from the family connections, some of whom suspected that the disease was one of the manifestations of syphilis, though the man had presented no previous evidences so far as is known of this disorder, and his children, a daughter and the son who is the subject of this paper, as well as a still-born child, which was delivered at about this period were all without known appearance of syphilitic taint. The living children have never to this date shown the indications of any form of syphilitic development. I have been inclined to think that the serious attack affecting the father at that time may have been Beri-beri, though I am not in a position to defend this opinion in a satisfactory manner. The father was sent home on his own ship, but under another master, and on arrival he was discharged as incapacitated for the position of captain. For a time he remained quiet, but at length after some months, he began to exhibit a roving tendency, and drifted westward to the mining districts, where he died after a period of about two years. The nature of his last sickness is not known to his friends.

The mother of the patient is living, and is well. She has never been remarkable in any way, but might be called somewhat erratic. The grandparents on the mother's side are both still living, and have always maintained an enviable reputation for intelligence and general information.

As a child of tender years, this boy presented peculiarities which were spoken of as evidences of unusual intelligence, but which now seem more like the preliminary symptoms of defective or disordered mental or moral equilibrium.

The first thing to claim medical notice was the tendency of the child to devour strange and indigestible substances, so that a careful watch was for years kept upon his movements, from the fear that he would swallow things which would cause injury either to the stomach or to the general health. As soon as he became old enough to go to school, which owing to his precocious growth, and advanced intellectual development was at a period much earlier than children in general would be sent there, his uncontrollable desire to swallow strange things was widely extended, owing to the greater ease of accomplishing any mischief, and the larger array of objects within access. His books were always coverless, and often the half of an entire volume would be absent, it having been devoured during school hours. To these substances were soon added portions of hair, pieces of blanket, the fuzz or lint from clothing, portions of wood, chalk, plastering, and other similar and equally incongruous articles in greater or less amount. The indulgence in a diet composed of such materials, gradually led to a chronic irritability of the stomach, so that after a short time the patient would be subject to attacks which the family called "bilious turns," during which I have usually been summoned, and have invariably found that the distress of the patient was relieved by the administration of an active portion of the powder of ipecac. The nausea and vomiting which followed, were the occasion of so great a degree of comfort, that the patient soon regarded emetic remedies not only without disfavor, but with positive relish, as the means of sure and complete relief to his temporary

¹ Read before the Boston Society for Medical Observation, December 5, 1887.

² I am not entirely satisfied with the title which appears at the head of this article, and have endeavored to find one more appropriate to the case herein described, but without success. The following correspondence will show that I am not alone in the desire for a more correct nomenclature:

BOSTON, 123 Boylston Street, January 24th.
MY DEAR DOCTOR.—Please excuse me for neglecting to return your paper sooner. I am greatly obliged to you for permitting me to read it, and am much interested in the case. Your view of the boy's present and prospective condition can be the only one, and I am afraid that those who pretend to be his friends and defenders now will find him out if they have not already done so to their cost. I wish that I could suggest a better name than "moral imbecility." It does not seem to quite fill the bill, but I can think of none that will answer better. Yours sincerely,
GEORGE F. JELLY.

distress. The vomited matters always contained more or less of the materials above mentioned or other similar substances, and fragments of woollen hair, etc., were frequently detected. The vomitus was never large in amount, sometimes dark colored, and once or twice was reddish as if it contained a slight admixture of blood. This last was, however, never present in greater quantity than would be properly expressed by the term, traces, and was seldom observed at all. Recovery from these attacks was always prompt and complete, and the health of the patient would become fully restored, so to remain until the irritability of the stomach again called for an emetic. During this period, the appetite was capricious, the strength not what would be expected in a boy with the vigorous frame of our patient, and the general vitality was not in correspondence with the physique.

At about this time the parents and friends of the child became sensible of various peculiarities of his disposition and character which they had not before observed, though it is quite within the range of probability that these strange traits had long belonged to the mental constitution of the patient. One of the most prominent, because the most annoying, was the inclination to dress in all kinds of strange and unusual costumes, often adopting the dress and even the under-clothing of other persons, of visitors, or even of persons of the opposite sex for the purpose of carrying out his desires in this direction. Soon he would wantonly take articles of value and unnecessarily damage or mutilate them in his endeavors to follow the dictates of his taste in dress. The silks and other fine dresses of his aunt and of other members of the family were often missing, and would only be found after long search, and then frequently rolled and jammed together, crowded in some out-of-the-way corner, with perhaps a jar of preserves, or a quantity of cake, or a blacking brush within them.

When remonstrated with on account of his unnatural and inexplicable conduct he would be totally unable to give any reason for such acts, and readily promised that he would certainly mend his ways, and do nothing of the kind again, and at once would, perhaps commit the same or a similar misdemeanor. Later he became even more wanton in disregard for the proprieties of his own position, or the rights and privileges of others. He took the jewelry of his aunt, who had always been very kind to him, and, going into the backyard, he hammered it out of all resemblance to ornament, utterly ruining a valuable set of precious stones. He soon began to steal, at first small things, and a little later took whatever he could obtain, using the articles stolen for his own purposes, without consideration of their source, or their suitability to his requirements. Soon after this he began to steal money, and to expend his ill-gotten wealth in the purchase of articles which pandered to either his eye or his palate. At length he commenced to steal for the purpose of selling the articles stolen, and thus obtained the means for further gratification of his unbridled propensities. He took a valuable chain belonging to one of his relatives, and, selling it for a paltry sum, he hired an expensive carriage, and went calling on all his acquaintances. On being questioned in relation to his doings, he would give the most plausible and apparently artless explanation of everything in connection with the entire affair, and would often force the conviction upon his interlocutor, quite against his reason, that the youth

had been unjustly accused of irregularity in his methods. When brought to bay, however, and on finding that subterfuges would not avail, he would, in the most simple and unaffected manner, confess the whole affair, and apparently acknowledge much more than he could possibly have committed, with an appearance of innocence of any wrong intention, which was at the same time surprising and exasperating.

He now entered the public schools, and a new direction was at once opened before him for the exercise of his evil propensities. He often came home richer in pocket than when he went away, and at length it became a matter of regular daily routine to make an examination of his pockets and to try to restore to their proper owners the various articles often found therein. Sometimes he would bring home considerable sums of money, as much as thirty to forty dollars being found upon his body at one time. Reports of vicious practices to which he was found to be addicted soon reached the ears of his parents, and he was at length expelled from a good school because he had been detected in teaching evil habits to his associates. On being asked about it, he at first denied all knowledge of the matter, but, on being pressed, he not only acknowledged the things of which he was accused, but also freely confessed other wholly unsuspected vicious deeds, the commission of which was, to me at least, quite problematical.

At this time he was an acknowledged masturbator, and stated also that he had had immoral relations with some of the girls of the neighborhood in which he lived.

He was now between twelve and thirteen years of age, and was already undergoing the changes incident to puberty. The genitals were rather more largely developed than is usual in youths of completed puberty, there was a small amount of pubic hair, and the appearance was that of a boy of fifteen, rather than that of one of twelve years.

He was placed in another school somewhat remote from that he had formerly attended, in the hope that new and different associations would improve him, and that his intellectual faculties might be stimulated by contact with those who were not conversant with his previous history, and thus a healthy turn be imparted to his acknowledged mental capacity. These hopes proved, unhappily, only too delusive, and before long the boy was again detected in possession of large sums of money, to which he had no lawful claim, though, as before, he would account in the most plausible manner for every inconsistency in his behavior, or for any strange variation in his worldly wealth. He broke into a church and wantonly soiled the premises, and stole the contents of the contribution boxes. He began to wander about in the vicinity, and would often be gone all day on expeditions of which he could or would give no satisfactory account. His family now lived in a state of alarm, from the constant impending danger of public disgrace, which was continually threatening them on account of the thieving propensities of this boy, and it became a serious question what to do with him. Many suggestions were advanced, only to be dismissed as either impracticable, or as too expensive, or as unsuited to his temperament or the condition of his health; and the subject was still as far from being decided as ever, when a train of events was inaugurated which at once and finally put an end to all deliberations of this character.

During the period just previous to this time, and extending through an indefinite term of weeks and months, there had become noticeable several distinct but not obtrusive changes in the disposition and character of this boy. His frame, which was large, was not filled out to the degree which was proportionate to the figure he should make. His complexion had become markedly pale and waxy, the lips and tongue were paler than usual, and, what was more striking than anything else, there was a growing restlessness of the eyes, with an increasing vacancy of expression, so that it became at times impossible to know if he were observing what was going on around him. There was less animation in his appearance than formerly, and he moved less readily, though he was not slow to follow the dictates of his inclinations toward any object which might lead to their gratification. He had solemnly promised to leave all the vicious habits he had contracted, and for some time asserted and maintained that he had wholly overcome them, and was free from their baneful influence. He was placed in another school, where he did exceedingly well, and brought reports from his teachers which were a source of great satisfaction to his guardians. The school being some distance from his house, he was obliged to travel by the cars, and thus was thrown among entirely new surroundings, and seemed to have formed new and better associations. All through this period, however, there were gradually developed the tendencies toward a greater recklessness, with the indications of a ferocity of disposition which had not been apparent before, and which was a source of much enigmatical speculation to his family and friends. This was laid to the fact that he was changing from boyhood to manhood, and was considered to be due to that restlessness which often accompanies the physiological changes of this period of life. It was hoped that the constant influences for good would so modify his tendencies that with the accomplishment of these processes in the system, there might be a subsidence of his evil propensities, and that he might thus reach the end of his mental and moral disturbances. These hopes were, however, suddenly blasted by the discovery that the boy was again indulging his thieving propensities, sometimes bringing home large amounts of money, which he would plausibly affirm he had found in the street, and intended to advertise, or would explain in some other equally reasonable manner.

At length, the evil became so threatening that it was the opinion of every one that measures must be adopted to check it at once. The final recourse in this family was the grandfather, who, though devotedly attached to the boy, was a strict and consistent disciplinarian, and had in former times been the only power which the boy had heeded or dreaded in relation to his misdemeanors. On one occasion, therefore, when the boy now appeared with a considerable sum of money in his pockets, and was called to account for it, he was told that he would be brought for his misdeeds before the grandfather, and that he could not sit at breakfast with the rest of the family, but would be obliged to take his meal alone, and then would be summoned to the parlor, where his case would be attended to. During the breakfast, the family was startled by a loud report and a heavy fall, and on hastening to the second floor the boy was found unconscious, lying on the floor, and bleeding from a wound

in the breast, just below and to the outside of the left nipple. In his hand was a small firearm of the bull dog pattern, which was still smoking, and which contained the empty shell of a cartridge. The boy was placed in bed and heaters quickly applied to the feet, and the nearest surgeon summoned, to whose care the first steps by which the safety of the patient was rendered greater from shock, and most of all, the application of an antiseptic bandage, is due, and to whom the family and I, myself, feel under the greatest obligation. I saw the boy very soon after the accident; but at that time there was very little to do, except to watch and wait, and after assuring myself that the boy was not at that time bleeding, I left the patient in charge of a trained nurse. I will here say that I have never so fully and clearly recognized the vast importance and the true value of the institution which has been created and supported by the efforts of some of the members of this Society, for the registration and furnishing of competent nurses, as on several occasions of extreme emergency, such as the one I have here described, in which the members of the patient's own household are entirely incapable, as in this case, of rendering any assistance, and where from the nature of the case there are complications which demand the intelligent and constant watchfulness of an educated and reliable person. The nurse supplied from this Bureau was all this, and I take great pleasure in thus testifying to the efficiency of the service by which such unexpected and trying demands upon its resources, as well as upon the nurses themselves, can be so promptly and satisfactorily fulfilled.

When reaction had been to some degree established, a careful and gentle examination of the chest was made, but no wound of exit of the ball could be found. There was a point of great tenderness at a place just at the outer border of the scapula, at about the level of the eighth rib, but the tissues were swollen to such an extent that no proper examination of the part could be made. The condition of the patient was too critical to warrant any unnecessary attempts at minute diagnosis, and the whole matter was left in suspense till a more favorable period. For some days there was coarse crepitation over the lower part of the left chest, but with the rallying of the system an abundant bloody expectoration was established, and the rational signs of that side diminished in severity. The bullet-wound healed kindly, and after two weeks the boy could be moved in bed and changed to a couch with ease. Soon, however, there appeared the signs of fluid in the left chest, and ere long there were unmistakable signs of compression of the lung on that side. The heart was displaced to the right, and breathing was much interfered with. Aspiration revealed the presence of serum, which, later, was replaced by purulent fluid. Hectic now was a prominent feature, the patient became much emaciated, and at length a permanent opening was established by operation in the ninth intercostal space, just posterior to the axillary line, through which large quantities of horribly offensive, purulent fluid were discharged. The chest was frequently irrigated with a weak solution of chlorinated soda, a portion of which returned through the opening in the chest-wall, while a part of it was expectorated from the mouth. At this time it was possible to make a more careful examination of the painful region in the left back, to which attention was directed at the

time of the injury. It was observed that when the scapula was strongly rotated forward, there was rendered accessible a portion of the sixth rib behind, upon the body of which could be plainly felt a distinct formation of callus, such as is ordinarily noticeable after the fracture of a bone, and it was concluded that the bullet had passed through the cavity of the chest, and, striking the body of the sixth rib under the shoulder-blade, had fractured it, and that the bullet had then passed in some other direction, as no trace of it could be felt at that point, and no wound of exit could be discovered at any time.

An acute traumatic pericarditis supervened upon the immediate symptoms caused by the bullet, which lasted with great severity for about two weeks, occasioning the effusion of a large amount of pericardial fluid, and preceded by the most exquisite cardiac friction-sounds. This subsided in about two weeks by the aid of small blisters over the front of the chest, and digitalis internally.

From all these severe conditions, and after much suffering, our patient made a slow but steady recovery, and after ten months was apparently as well as before the injury. He was, after much anxious deliberation on the part of his family, once more placed in school, at one of the so-called "colleges" of this city, where he made good progress in his studies, and again raised the fondest expectations of those who were interested in him. Suddenly, upon some slight provocation, he rose from the table, and leaving his meal untasted, took his departure from his home, going to the house of a neighbor in the vicinity, with whom he had long been on most friendly terms. Here he was cordially received, and his cause being espoused by his new protectors, he found the change to be the occasion of no small amount of localized notoriety, and apparently enjoyed the attention of those about, of which he was the principal object. He wrote insulting letters to his aunt, who had reared him from childhood, he reviled his family in no measured terms, he added injury to injury, and made no small disturbance in the neighborhood by the outrageous tales he narrated of the doings of his own relations. In all this he was unfortunately aided and abetted by the members of the family into whose bosom he had been received, and who took no pains to conceal their partisanship with their guest. On being remonstrated with by his aunt, the boy wrote obscene and disgusting letters to her.*

in which he expressed the wish that certain members of his own family might soon die, as he thought they were not very happy on earth; and in other ways added to the distress of those to whom he was attached by the strongest ties of blood and relationship. After a residence of a few days, or possibly weeks, in his new home, this boy of fifteen years and two months was married by a *clergyman* to the daughter of the family with whom he was stopping; his wife being aged some twenty-three or twenty-four years. The marriage was performed without the consent of the boy's mother or her knowledge, the marriage license being taken out in another city of this Commonwealth, in which the ages of both the contracting parties were given under oath as nineteen years. Since this unannounced event the boy has once or twice been the subject of medical observation. He is now pursued by hallucinations of persecution; he imagines that he is to be kidnapped; he has the most exalted views of his own importance; and presented himself at the house of one of those whom he had outrageously insulted for the purpose of obtaining some assistance, and on being reproved for his former conduct repeated the offence.[†] He has not entered his former home; he is thus far supported by the family to whom he has attached himself, he contributing a small sum of money which had been deposited in the bank by his relatives at various times, as his share of the family maintenance. This stipend is now at an end, and thus another element is added to those which are operating to induce a new eruption of violence in this patient, which surely cannot be long deferred, and which is already the subject of anxious solicitude on the part of his relatives.

We have here the history in this far, of a boy who was early distinguished by the marks of disproportionate development, in which I conceive the idea of precocity mainly to exist, and which was distinguished in its first stages by a certain degree of perversity of sexual tendencies, as evidenced by the strong desire for the pleasures usually accorded to girls, and decidedly unsuited to the sports of boys. To this was then added the propensity to maliciously hide and disarrange things with which he had no concern, then to steal things which he could not use, and which he would at a later period endeavor to convert into the means of his personal enjoyment, with no consistent view to their value or the associations with which they might be connected. Soon a pronounced tendency to falsehood was developed, in which the boy became

to see how it concerns us in any way, as my home is with her and her family, and I will never go elsewhere. This letter is the last of any connection between us. I shall return your letters unanswered or opened, as I wish to hear nothing of any kind from you. I hope my grandmother will soon die, for she has no peace on this earth. I am obliged for your kind offers of assistance or aid or counsel, but my lawyer will furnish the latter. My best friends the former. And paying that money you owe to others show that mercy show to I, remain yours, etc.

ARTHUR L. K.

* Letter No. 1.

† Letter No. 2.

DEAR MADAM,—Your favor is at hand, and while thanking you as a "disinterested party" for your kind advice, will respectfully inform you that I consider it a waste of words. I left the house of your father because of the impurity of his conversation and his brutal cruelty to his family. As to entering his house again, I never will, on any pretence. My mother, as you yourself acknowledge, is not a proper person to have the care of me. I am at present in a home among refined people, superior in every respect to those with whom I have been accustomed to associate. You have been abused and kind to me, and I am not a fit person to be longed for your behavior in that time. I never want to see your face, or any member of the family again. I also wish to inform you that "Miss W.—" is neither a confirmed invalid, nor is our engagement in any "ridiculous absurdity" to any one. I wish you to know that I am not in any way influenced as your letter states. You see no truth in it, and I am not a fan or fool. Don't you think I saw and know you, and understand you fully. Now I will inform you as to my past conduct, and then you and my mother call me an audacious, fierce, and cruel boy. It is too ridiculous. I have committed adultery a numberless times at the barn on F— Street and at P—'s barn, and at houses of all kind in Boston, and when at L—'s school, one of the girl pupils was familiar with me in the same way. I have stolen a great deal of small sums of money from Mrs. —, my present mother-in-law—Ed., and she kept it to herself. Miss W.—'s friends are all people of refinement, and certainly look on her choice with horror. You know there are few in the town who do not know me, and she has been pained many times at their remarks concerning me, but she loves me, if it is a piece of "sentimentality," and has braved all, and I fail

* Letter No. 1. To the aunt, who had cared for him during many years in the most tender manner:

DEAR MADAM,—Your favor is at hand, and while thanking you as a "disinterested party" for your kind advice, will respectfully inform you that I consider it a waste of words. My mother, as you yourself acknowledge, is not a proper person to have the care of me. I am at present in a home among refined people, superior in every respect to those with whom I have been accustomed to associate. You have been abused and kind to me, and I am not a fit person to be longed for your behavior in that time. I never want to see your face, or any member of the family again. I also wish to inform you that "Miss W.—" is neither a confirmed invalid, nor is our engagement in any "ridiculous absurdity" to any one. I wish you to know that I am not in any way influenced as your letter states. You see no truth in it, and I am not a fan or fool. Don't you think I saw and know you, and understand you fully. Now I will inform you as to my past conduct, and then you and my mother call me an audacious, fierce, and cruel boy. It is too ridiculous. I have committed adultery a numberless times at the barn on F— Street and at P—'s barn, and at houses of all kind in Boston, and when at L—'s school, one of the girl pupils was familiar with me in the same way. I have stolen a great deal of small sums of money from Mrs. —, my present mother-in-law—Ed., and she kept it to herself. Miss W.—'s friends are all people of refinement, and certainly look on her choice with horror. You know there are few in the town who do not know me, and she has been pained many times at their remarks concerning me, but she loves me, if it is a piece of "sentimentality," and has braved all, and I fail

marvellously adept, and which he would exercise with the most unblushing assurance and under the most unpromising circumstances. Then came the propensity to steal from other than the members of his own family, and with this the increased danger of detection and punishment. At this time the sexual functions were aroused and unbridled license given to various injurious habits, and even the prostitution of the girls of the neighborhood was attempted, if not accomplished. He now presented signs of constitutional disturbance, in the white waxy skin, the vacant eyes, the abstracted air, the ready plausibility of all his ideas, the self-satisfaction which was a prominent feature of this period, and with all this there was an increasing recklessness of demeanor, and an augmented tendency to run any risk, to undertake any scheme, which marked a new epoch. The threatened punishment led him to seek escape by suicide, though whether this was done from a feeling of overpowering momentary terror or as a sudden impulse in the direction of remorse, we will not attempt to decide. Enough, that he did not hesitate to bring distress upon himself and others, for a comparatively insignificant cause. His long illness and slow convalescence gave him time and opportunity for meditation, and he seemed to have undergone a radical change in his disposition, until he was again able to go about, when the old impulses gradually assumed control of his acts, and he drifted into sexual vices, soon to leave his home upon the most insignificant pretext, and at a little later period to become the child-husband of a woman many years his senior.

I think that he is hardly to be held accountable for some of the acts committed since leaving his home, for he seems to have been brought into contact with "seven devils worse than himself," by whom he has undoubtedly been injuriously influenced, and to whose unwholesome association is to be laid the commission of some of his erratic actions during this period. The fact that the father and mother of an invalid girl would not only countenance a marriage such as was here consummated, but would even wink at perjury for its attainment, would seem to indicate that the misguided youth thus transformed into an infantile husband was not the only moral imbecile in this strange household.⁵

⁵ Letter No. 3.

DEAR MADAM.—I feel now that it is my duty to inform you as to Arthur's marriage which was consummated the first day of the present month. I am very sure you must have been aware of the great love he had borne Grace for over a year, and he has by his great tenderness and fidelity that she would never give to another, her undivided love, and although she is a few years his senior, she is undoubtedly by far the younger in her child nature. She is simplicity itself, and well may Arthur and all those connected with him be proud of such an alliance. Although Grace is not surrounded by wealth, she is proud to say could grace a mansion as she is a lady in every sense of the word and not a girl as you spoke of her. I think you or the family could never have known who Grace's friends were, and Arthur will certainly through his wife be able to enter circles which he had never been accustomed to before. I am sorry to inform you that the marriage has been kept silent from even my own family as they would be so indignant at one like Grace giving herself to one that had led such a fearful life. You have never inquired of Arthur who he met here, therefore you are not aware that they are all people that are cultured; and most of them of wealth. I am surprised that you look upon us in the light you do and could you see my relatives I think you would be surprised. Grace came from a fine old English family and as we English look at the blood and not the money Arthur has not in any sense devalued himself. I can assure you that he is loved by all with great devotion; as for myself I would do anything for him. He told Grace if she did not marry him he did not care what he did, he should go right to ruin. She has been his savior and no one else could do for him what she has done and will do. I have told her she has a long task before her and a most tedious one, but she does not shrink from it. I do not think even you know the fearful sins he has committed, they have been something fearful and unfit for one to know. He told me all before he married my child, and still I allowed it, only God knows why. Miss G. if you love him be thankful to Him above that he is now out of sin. Arthur married of his own free

The above case is presented at this time, and with this much of detail for two principle reasons: First, in order to place upon record the observations made by somewhat careful study during a period of twelve years, upon a case of moral perversion originating in childhood, and increasing with the age of the individual, bearing a close relationship in its course with the development of the physiological instincts and passions and leading through a series of abnormal acts to its culmination in the attempt at suicide. Both before and after this desperate act, there is evidence of a change in the tendency of his feelings, which had been formerly directed toward himself as their object and end, but which later have exhibited an unmistakable direction toward external objects and things, with the result of an augmentation of danger to those about him, or with whom he may be brought in contact. The consideration of the past career of this unfortunate boy, and the study of his present condition, point with prophetic certainty to the commission of other acts dependent upon a perverted moral sense, and I deem it my duty to place upon public record the facts thus far obtained, and to declare my positive opinion that the individual to whom this paper relates, is the victim of some radical moral defect, and is not fully responsible. It is my belief that he cannot possess a proper and healthy appreciation of the nature and the consequences of some of his voluntary acts. I also do not hesitate to predict that this unfortunate boy will become more and more unmanageable and reckless as time goes on. I consider him a menace to the safety of the public at this time, and think that he should be placed under proper restraint, both for his own safety as well as for that of others. I believe him capable of performing any act of violence, from real or imaginary provocation, and do not think he would hesitate to employ any means of satisfying his malice or seeking revenge. These considerations lead to the presentation of the second reason for the publication of this case. This takes the form of a question: What is the duty of the medical adviser in a case of this kind? I am obliged to assume the responsibility of the care of a dangerous person, and feel that the welfare of a number of persons is in constant jeopardy, and I find myself powerless to act for his restraint. When the expected calamity has occurred, and the entire community is aroused by some shocking crime against person or life, the medical man will quite probably be subjected to harsh criticism for having omitted to take active measures for the proper restraint of an individual known to be dangerous. The way to procure the confinement of the suspected individual is not clear, as the family of the patient is not disposed to attract public attention by instituting proceedings for his commitment.

During the discussion of this paper by the members of the Boston Society for Medical Observation, in which an animated debate was carried on, the undivided opinion was expressed that the only safe and appropriate manner of dealing with this case was to move for immediate restraint of the patient, and his permanent commitment to some secure retreat, both will and he told me if he did not he would kill himself. He said he attempted it once and he should do it again if Grace did not love him. I think could you have seen her that day you would have said "a lamb given to the slaughter," she looked so holy in her white gown. They are both young and happy why put any stumbling block in their way.

I enclose two of Mrs. H's letters; she is very wealthy and has looked forward to having Grace with her when she became better, but God has willed it otherwise.

for the safety of himself and that of others; as well as to preclude the probability of procreation on the part of an individual of this kind, by which the moral infirmities of the present patient might be transmitted in an intensified form to the offspring. No way was suggested, however, by which these desirable results were to be obtained, and I see nothing to do but to wait for the next explosion of the disease, which I fear will not be long delayed, and which may, by its character force the inauguration of measures for the seclusion of this dangerous person.

THE REINFORCEMENT AND INHIBITION OF THE KNEE-JERK.¹

BY H. P. BOWDITCH, M.D.,
Professor of Physiology, Harvard Medical School.

THE familiar fact that a blow upon the ligamentum patellæ causes a sudden contraction of the extensor muscles of the thigh became an object of careful physiological study when its diagnostic importance was pointed out by Erb and Westphal.

One of the most important additions to our knowledge of the phenomenon was made about two years ago by Drs. S. Weir Mitchell and Morris J. Lewis,² who, directing their attention to a phenomenon first pointed out by Jendrassik,³ showed, in a series of carefully conducted experiments: (1) That the so-called knee-jerk can be increased by volitional acts directed to other parts of the body; (2) that volitional reinforcement lasts for an appreciable time after volition ceases; and (3) that continued violent muscular acts at last enfeeble the knee-jerk, and this enfeeblement lasts for an appreciable time.

These conclusions suggested the importance of studying the exact relations in time between the knee-jerk and the reinforcing act since we might reasonably hope to obtain in this way some insight into the nature of the mysterious processes having their seat in the central nervous system; and the object of this communication is to present to the Academy a preliminary report of the results of some experiments recently made in the physiological laboratory of the Harvard Medical School by Dr. J. W. Warren and myself with the hope of throwing light upon this subject.

A detailed description of the apparatus used need not be given in this connection. Suffice it to say that the blow upon the ligamentum patellæ was delivered by a light hammer, (Fig. 1, H) fixed upon a splint-like covering enclosing the lower leg. By this arrangement a certainty that the hammer always struck the same point during each experiment was secured. The force of the blow was regulated by the tension of a spiral-spring S, which drew the hammer toward the knee when it was released by the breaking of an electric current controlling a magnet, M, also attached to the covering of the leg. The straps B B B served to secure the apparatus to the leg, and the rings L L to suspend the leg from the ceiling as shown in Fig. 2.

The individual to be experimented upon lay upon his right side, with the left knee slightly bent (Fig.

2), and the internal condyle of the left femur resting upon a fixed support, the position being essentially the same as that adopted by Lombard.⁴ The weight of the lower leg was borne by a cord hanging from the ceiling and fastened to the splint-like apparatus on the leg. The lower leg was thus free to swing in a horizontal plane round the knee-joint as a pivot, and its movement, reduced by a system of levers to one-sixth of its extent, was recorded by a pen (P) upon the smoked surface of a cylinder revolving once an hour. A pendulum myograph (D) served to break two electric circuits as it swung by striking against two keys adjustable at various points in its course. One of these circuits controlled the magnet holding up the hammer at the knee, and the other an electric bell (B), a stroke of which, on the breaking of the circuit, was the signal for the reinforcing act. Thus, by varying the position of the keys, it was possible to secure any desired interval from 0.0" to 0.5" between the reinforcing act and the knee-jerk. Where longer intervals were required, a pendulum vibrating more slowly than that shown in the figure was employed.

Figure 1.

The reinforcing act was a short, vigorous, clinching of the right hand upon a piece of wood, shaped somewhat like a tuning-fork, and furnished with metallic tips so adjusted that a slight pressure would bring them into contact, and thus close the same electric circuit that was opened when the bell was struck. As this circuit also included a Depriz signal-magnet writing upon the smoked surface of the pendulum myograph, a record was obtained with each experiment of the reaction-time of the individual to an auditory impression.

This reaction-time, of course, includes a centripetal, a central, and a centrifugal portion, and as the total duration was liable to considerable variation, and as, moreover, it was impossible to say in advance which portion of the reinforcing act would have the greatest influence upon the knee-jerk, it was decided to regard the stroke of the bell as the zero point of the reinforcing act, and when this point coincided in time with the blow of the hammer upon the ligamentum patellæ, the interval between the reinforcement and the knee-

The Variations of the Normal Knee-Jerk. The Am. Journal of Psychology, Vol. I, p. 1.

jerk was called zero. The object of the investigation was, therefore, to ascertain how the extent of the knee-jerk would be affected by varying the interval of time at which the blow upon the ligamentum patellæ followed the signal for reinforcement. No experiments were made in which the blow preceded the signal, since it would be difficult, after receiving the blow, to wait for the auditory signal before giving the reinforcing act.

Figure 2.

Each experiment lasted, as a rule, about one hour. During this time several series of observations were made, each with a different interval between the bell-signal and the blow. Each series was divided into two portions, in the first of which there was no reinforcing act, and the knee-jerk was regarded as "normal," while in the second the individual responded to the bell-signal in the above-mentioned manner. The difference between the average extent of the knee-jerk in the first and second portion of each series was called the *special* reinforcement for the interval corresponding to that series, and the difference between the extent of the knee-jerk in the second portion of each series and in the first portion of *all* the series in the same experiment was called the *general* reinforcement for the same interval.

Figure 3.

Experiments were made upon four different individuals with the same general results in each case. The

nature of this result may be best understood by an examination of the curve shown in Figure 3, constructed from the record of 551 normal, and 624 reinforced knee-jerks in the same individuals. In this curve the abscissas represent the intervals between the bell signal and the blow, and the ordinates the difference between the "normal" and the re-inforced knee-jerks. Positive ordinates indicate an increase, negative a diminution of the knee-jerk.

The figures at the left of the curve show in millimetres the absolute amount of increase or diminution. The dotted curve is the curve of *special* reinforcement; that is, it represents the average difference between the reinforced knee-jerk and the *special* normal of that series, while the full curve is the curve of *general* reinforcement representing the average difference between the reinforced knee-jerk and the general normal of the experiment. Both curves follow, it will be observed, the same general course, and show clearly that if the blow follows the signal at an interval not greater than 0.4" the reinforcing act increases the extent of the knee-jerk. If the interval exceeds this amount a diminution of the knee-jerk results. If, however, the interval is prolonged to 1.7" the reinforcing act is without effect upon the knee-jerk. To express the same conclusion in other words, we may say that, when by a brief act of volition the muscles of the forearm are innervated, the spinal cord is thrown into such a condition, that that portion of it which is concerned in the production of the knee-jerk is for a short time in a state of exalted activity which is succeeded by a period of depression and then by a slow return to the normal state.

We thus find the activity of one set of nerve centres serving first to exalt and then to depress the activity of a neighboring set. Without speculating upon the nature of the processes thus reacting upon each other it may be well to point out that we have in this alternating action a phenomenon which cannot fail to throw light upon the nature of "inhibition" and destined perhaps, when fully understood, to establish the interference theory on a firm basis.

In this connection also, should be noted the observations of Meltzer on the inhibition of the peristaltic movements of the oesophagus by a rapid succession of movements of deglutition.

It is evident that a wide field of research is open and that the various modes of activity of the central nervous system should be studied with reference to their effect upon the knee-jerk, and it is not too much to hope that careful experimental work directed on these lines will dispel a portion of the mystery which now surrounds the function of the nerve-cells.

— By the latest statistics, there are 11,997 physicians in France. About one-fifth practice the new dosimetric (alkaloidal) treatment, one-tenth are homœopaths, and about one-twentieth hydropathists.

PNEUMOTHORAX, WITH AUTOPSY, IN A SUBJECT WITH EXTREME RETRO-LATERAL CURVATURE OF THE SPINE.¹

BY HORACE E. MARION, M.D.

MARCH 28, 1886, I was called to see C. A. N., a clerk, age forty-three. He has angular postero-lateral curvature of the spine, supposed to be from injury in infancy.

On the 24th (four days before), while at work at his desk, and after partaking of a moderate lunch, he was attacked with a severe pain piercing his right lung. (The curvature has its convexity to the right.)

He got up, moved about the office, and after a short time resumed his work. On retiring that night he felt chilly, but made but little account of it; indeed, he went to town next day, and worked at City Hall all day. The day following he remained at home, but on Saturday (27th) he worked all day, and in the evening attended a Masonic meeting.

I found him (28th) sitting in the bed, suffering from such severe pain that he was unable to lie down. Pulse 90 to 100, temperature 101°. No cough, hurried and shallow respiration. Flatness at base of right lung (the chest is so elongated antero-posteriorly that the dullness may have been natural). The chest is extremely asymmetrical. Friction-murmurs in axillary line, about the sixth rib.

April 5th. Temperature and pulse have remained about the same, with relief to the severe pain. Pulse 90 to 100, temperature 99° to 100°. Friction-murmur has been very distinct along the fifth and sixth ribs. Yesterday, that is, a little more than ten days from the first symptoms of pain, while drinking milk, some went, as he said, the "wrong way," causing him to strangle, cough, and vomit. To-day, examination shows tympanic resonance over the greater portion of the right chest, metallic tinkling, amphoric respiration and voice, with also succussion-sound. Much distressed after lying in one position for any length of time, or after sleeping.

April 7th. No special change. Friction-murmur can still be heard. Severe pain after sleeping, or in attempting to change position, extending to back and shoulder. Pulse 90 to 110, temperature 99° to 102°.

April 8th. Dr. F. I. Knight saw him in consultation. He found pleuritic friction, effusion, and air within the chest; as he expressed it, an unusual combination in acute pleurisy, and one not easily accounted for.

April 12th. Fair night, but complains of pain in back, that his back is broken in two; somewhat delirious. Respiration 44, face puffy, skin moist and slightly cyanotic. Aspirated, removing three and one half pints of offensive pus; during the escape of the last half pint, air escaped through the tube with considerable force.

April 13th. Had a comfortable night after 12 o'clock. An hour after aspiration he had a chill, and his temperature reached 104°, followed by profuse perspiration. Has no pain, and feels much better. Amphoric breathing and metallic tinkling.

April 16th. No special change, except that now he tastes the offensive pus when he coughs. The odor is noticeable in the room.

April 17th. Made a permanent opening, removing about three pints of extremely offensive pus. In-

serted drainage-tube, and dressed with bichloride gauze.

April 18th. Washed out the chest with solution bichloride, 1 to 3,000, and dressed with antiseptic gauze.

April 27th. Since the permanent opening the temperature has been but once above 99°, most of the time 98½°. The pulse has remained frequent, about 100. Respiration from 30 to 35 in the minute. Removed the tube.

May 29th. Still discharging; can easily introduce bougie within the chest. Respiration good in front and back: flatness below the level of the opening. Coughs a good deal. During the past month the temperature has ranged from 98½° to 100°. Pulse and respiration always accelerated.

June 1st. Has been out when the weather was fine.

June 7th. Opened an abscess below and in front of the original opening, with which it is connected.

June 13th. His condition not improving satisfactorily, and after counsel, gave ether and enlarged the opening into the chest. No pus was found. Drainage-tube left *in situ*.

June 15th. Pulse 120, temperature 104°, respiration 30. Some pain on sneezing, taking a long breath, and in gaping. Coughs, and raises offensive matter on rising in the morning. No appetite. Almost no discharge from the side.

June 21st. For the first time, seems to feel better; temperature and pulse normal. No discharge.

June 23d. No discharge. Tube left out. Still expectorates offensive pus. A few riles, moderately coarse, can be heard just beneath the clavicle.

June 26th. Considerable offensive discharge from the sinus.

June 28th. Still discharging large quantities of offensive pus from the side. Washed out the chest and re-introduced the tube.

July 18th. Still coughs a little, and expectorates a little purulent matter in the morning. Tube out. Can easily pass bougie into the chest.

From this date he improved constantly, though slowly, until quite recovered, so as to resume his work about the middle of September. The opening in his side did not close until about the first of October.

From this time until June 1, 1887, I saw him frequently, but not professionally. His widow informs me that: He was able to attend to his regular duties at City Hall all the time; that he was quite well during the winter. In January he suffered from "teeth-ache," for which he consulted a dentist and had some teeth extracted, with no relief to pain. Many of the teeth became loosened, but did not decay. Complained of severe pain of his right shoulder and back at times. In February, the wound in his side reopened and discharged a little thin, sero-purulent matter, and remained open ever after, except during July and a part of August.

In April and May, had an attack of what passed as dyspepsia. He was thought to have lost flesh and strength ever after February, when the wound reopened. About this time, he began to have night-sweats more or less constantly. His cough was slight, never troublesome, but he never was a long time without some cough, although he made no account of it.

June 1, 1887. I was again called to see Mr. N., on account of a painful swelling just below knee and to the inner side of leg. He was at his desk, writing;

¹ Read before the Boston Society for Medical Observation, December 5, 1887.

said it caused no pain unless he moved the leg. The irregular, cord-like feel, its depth, and the cellular tissue not being involved, suggested phlebitis. He was urged to take his bed, and a bandage was applied.

June 6th. He took his bed three days ago. Obligated to keep the leg in one position; cellular tissue becoming involved.

Physical examination of lung gives no new evidence. Fistulous track to what seems to be a circumscribed pleural cavity, still open. No cough to speak of.

August 20th. Since last notes, now more than a month, he has remained in bed all the time. For the first three weeks in June he did his writing (clerk for the assessors) in bed. Has lost flesh and strength. Temperature scarcely ever above 100°. Pulse 100 to 110.

Three pyæmic abscesses have been opened; namely, one below and one above the right knee and one on anterior part of left leg. Another over and just above the left trochanter should have been, but he would not allow it. Complains frequently of intense pain in right shoulder and in the back, which he says is breaking-in-two.

For past three weeks at least, has remained with his right thigh flexed in the pelvis. For past five weeks the opening into the chest has been closed or healed. Has had scarcely any cough until last night, when he coughed up a third of a teacup of offensive pus.

After a great deal of coaxing, I opened a fluctuating tumor just to the right of the fourth lumbar vertebra. About a pint of offensive pus was evacuated, and a drainage-tube introduced, extending along the crest of the ilium to its anterior spinous process.

September 4th. He consented to-day to have the tumor over the trochanter aspirated: one-half pint of matter was removed. Gradually losing ground.

October 17th. Has failed more rapidly lately. To move him has caused excruciating pain. For days past his death has seemed imminent.

This morning, not having syringed out the pus cavities for the past two mornings on account of his extreme weakness, I got him up on the side of the bed as usual and commenced; the first water thrown into the opening low down in the back seemed to strangle him and I desisted. I got him back into the bed bolstered up with pillows, but he died within an hour.

Autopsy, twenty-four hours after death. Right postero-lateral curvature of spine. Emaciation extreme. Rigor mortis marked. Right thigh flexed at an angle of 50°, with horizontal plane of body. Thin pus exuded from an opening just above right knee, at inner side of right calf, over middle and front of left tibia, over left trochanter, on a level with and to the right of fourth lumbar vertebra and at angle of right scapular. The curvature is such that the right scapular rests apparently upon the top of right chest. Over the angle of the curvature is an enormous bed-sore fully six inches in diameter, in which are exposed muscles, facie, and bone.

On removing the sternum and costal cartilages the left lung collapsed. The heart, a little further to the left than normal, was normal in size and general appearance. The pericardium contained about forty grammes of serum. Heart substance firm and valves normal. The coronary arteries much enlarged and atheromatous; atheromatous changes had also taken place in the aorta. The left thoracic cavity was

about three-fourths larger than the right. The left lung was vicariously enlarged and free from disease. The right lung correspondingly small was bound to the lateral aspect of the chest wall by a firm band which completely enclosed a pus cavity about four by six inches in size. Lung tissue, except for about an inch around this cavity was normal.

Nothing remarkable about the stomach, intestines or bladder. Spleen much enlarged, soft and friable. Left kidney twice the size of right, capsules easily removed, hyperæmic, but otherwise normal save at the upper convex border of the right, where small pus cavities had begun to form.

Liver was in size normal, but somewhat fatty. At the greater extremity or border, a change similar to that of the kidney had taken place. The necrosis of the liver and kidney was immediately in contact with a pus channel, to be described. Removing all the organs, it was easy to demonstrate a sort of covered way extending along the chest wall downwards, inwards, and backwards, from the opening between the eighth and ninth ribs at angle of scapulae to the angle of the curvature and to the bottom of pus-cavity. The angle of curvature was one of about 25° or 30°. The inflammatory tissue could be easily removed, leaving bare the vertebrae at the angle of curvature, exposing also the aorta in its course, which, by the way, passing over the convexity of the angle, lay within less than an inch from the opening into the chest.

This pus-channel continued along the vertebrae behind the liver and kidney, as before alluded to, to the right iliac fossa as far as Poupart's ligament, and backwards to middle of sacrum. The opening near the fourth lumbar vertebra communicated with the iliac fossa along the crest of the ilium. The inner aspect of the ilium was entirely denuded of periosteum, as was a portion of the sacrum.

I have reported the foregoing case inasmuch as it presented a few points of interest. I have designated it a case of pyo-pneumothorax, although I am not sure that at first it was not a case of hydro-pneumothorax. In both, the physical signs would be quite similar.

The sequence of events was as follows: Acute pleuritis, not wholly incapacitating the patient for work, followed by an effusion within four days, or prior to my first visit. One week later, or two days from the initial pain, there was positive evidence of air within the pleural cavity. Air was detected soon after his severe fit of coughing and strangling.

On aspirating the chest one week later, or seventeen days from the initial pain, the fluid proved to be purulent and offensive.

I would remark here that the deformity rendered it impossible to say exactly whether the heart was in or out of its normal position, and to fix definitely the line of fluid dulness. Five days after aspirating, or twenty-two from the attack, the permanent opening was made, with marked improvement to all his symptoms.

In ten days after introducing the tube it was removed, as everything had been absolutely dry for several days. This was thirty-two days from the attack. In thirty-four more days, or sixty-six from the attack, the opening was enlarged and tube left *in situ*, although the cavity contained no pus. In ten days more the tube was left out, but re-introduced at the end of five days, and soon discontinued altogether. For three months longer, or one hundred and seventy-five days from the first, the opening into the chest remained

open. Then followed five months of comparative good health, the opening into the chest being closed, and he able to attend to his work.

In a few days less than a year from his first attack, the side opened spontaneously at the place where the original opening had been made. Ever after this he lost flesh and strength, and the side remained permanently open, excepting about five weeks.

At the end of fourteen months he began to develop pyæmic abscesses, of which five, at least, were opened, one communicating with the pus-cavity in the iliac fossa, and this, in turn, with the pleural cavity. He died of exhaustion, hastened, perhaps, a few moments by my endeavor to make him more comfortable, in one year, six months, and twenty-four days from his first attack in March, 1886.

One point of interest is the cause of the pneumothorax; if, as I have already intimated, a rent in the pleura and lung was caused by the coughing and strangling, and through this rent air entered the pleural cavity, it may be looked upon as traumatic, and liable to occur at any time. On the other hand, if the rent in the lung was caused by the nature of the pleuritis or the character of the contained fluid, it renders the case more open to speculation.

We take it for granted and self-evident that pneumothorax is a secondary affection, inasmuch as there must have been severe injury or lesion to the pleura to allow of air entering the pleural cavity.

Pneumothorax, pure and simple, is but rarely met with, except for a short time, or in connection with fluid. This condition was recognized as long ago as the time of Hippocrates, and the physical sign caused thereby, namely, succussion, is often designated the Hippocratic sign.

Laennec divided pneumothorax into three varieties: First, essential pneumothorax results from spontaneous formation of gas in the pleural cavity; second, pneumothorax from purulent decomposition of the liquids effused into the pleura; third, pneumothorax from perforation due to rupture of the pleura, or to an accidental opening by which atmospheric air or gas from the lungs is introduced into the pleural cavity.

Notwithstanding this distinguished authority, it has been satisfactorily demonstrated that the pleura cannot secrete air or gas. As to the second variety, namely, the decomposition of the effused fluid, although at one time supported by such men as Hughes Bennett, Townsend, Wunderlich, and Jaccoud, it is difficult to understand how this can be, as the presence of air is the *sine qua non* of decomposition.

We are, therefore, left to accept the third variety; namely, the perforation of lung tissue. This may be traumatic, or it may be due to a pathological process going on in the lungs, pleura, or some adjacent organ.

That pneumothorax is not an infrequent occurrence in phthisis pulmonalis, all will agree. This not only from our own individual experience, but all observers state that phthisis is by far the most frequent cause of pneumothorax; Walshé says ninety per cent. Fernet² states that pneumothorax results in nine-tenths of the cases from some of the forms of pulmonary phthisis. Fraentzel³ says, from his own observation, that 90 out of 96 cases of pneumothorax are produced by vomica on the surface of the lung in the course of caseous pneumonia.

Lausier shows, in his frequently quoted table, the relative frequency of the principal causes of pneumothorax in 131 cases:

Pneumothorax with phthisis	81.
" " empyema	29.
" " gangrene	7.
" " pulmonary empyema	5.
" " apoplexy	3.
" " hepatic fistula	2.
" " hydatids	1.
" " hæmorrhage	1.

Here empyema takes second rank, which seems to be in keeping with common experience.

If this be the cause in the case I have reported, that is, if mine was a case of purulent pleuritis before the introduction of air, then it is not a particularly rare case. On the other hand, if it was a case of simple acute pleurisy with effusion, and the early introduction of air by traumatism or otherwise, then it may be classed as an unusual case.

Concerning the last illness, which may be considered as a sequence of the first, one is curious to know whether the termination would have been different had he not been a victim of spinal curvature; in other words, how much did the curvature of the spine contribute to the fatal termination. I regret that the vertebrae were not removed or examined more carefully *in situ*. Certainly, the point of curvature was and had been bathed probably in or covered by a pus-secreting surface for more than a year.

The tissues over the vertebrae, as well as the inflammatory products, were very easily removed, but I cannot say the bones were roughened in evidence of necrosis. The pyogenic process having dissected off the attachments of the diaphragm to the spine, the descent to the pelvis behind the peritoneum was easy. Certainly, the route from the bronchi and opening at the angle of the scapula to the opening near the fourth lumbar vertebra was sufficiently circuitous to be, at least, unique.

A CASE OF ABSCESS OF THE CEREBELLUM FROM EAR DISEASE.¹

BY J. ORNE GREEN, M.D.

PATRICK F., aged thirty-six. Mother died insane, father now in Danvers Asylum, also insane. No history of syphilis. He was kicked by a horse in right temporal region fifteen years ago; some brain symptoms, probably concussion, from which he soon recovered. As result of this kick right auricle is adherent to scalp by cicatricial tissue. Ever since this injury has had an otorrhœa on right, moderately profuse, but unattended by pain or external swelling.

The last five months has complained much of his head, especially in right temporal region. Entered Boston City Hospital, service of Dr. Sumner, in March, 1888, with partial paresis of all branches of right facial nerve of only a few days' duration, with head-ache referred to right temporal region; vomited more or less daily, especially at night, and apparently without cause. Intellect perfectly clear, appetite poor, bowels not constipated. Physical examination revealed nothing except the paresis of right facial, and the otorrhœa. The paresis entirely disappeared without treatment in four days.

I saw him on March 17th, and found the right meatus completely filled by polypoid growths, and the

² Nouveau Dict., Vol. xxviii.

³ Ziem. Cyc., Vol. iv.

¹ Read before the Boston Society for Medical Improvement, April 23, 1888.

next day, under ether, removed four large polypoid masses, one of which was attached to the posterior wall of meatus, and the rest apparently arose from the tympanum. Rough and probably carious bone was detected in the posterior and upper part of the tympanum.

He expressed himself as much relieved after the operation, and the headache and vomiting ceased entirely for two or three days.

The stump of the polypus was treated by *spt. vini*, and gradually was shrivelling up, and the ear was kept clean by antiseptic syringing. The tuning-fork on vertex entirely in right ear; no tenderness or swelling over mastoid. The headache and occasional vomiting soon returned, and up to his death were intermittent, continuing for twenty-four to forty-hours, then ceasing, only to recur again after an intermission of one or two days. Slight delirium was shown on one or two occasions about a week before his death, but was only momentary. In reply to questions he almost always said he felt "first rate." From the time of entering the hospital he always laid quietly, indifferently on the two sides, with his head covered in the clothes, and in a slightly somnolent condition, from which he was easily aroused. Sitting up immediately caused great vertigo, and if this position was maintained for several minutes vomiting resulted. On being asked to point to the seat of pain in the head he always placed his whole hand over the temporal and parietal regions. There was a slight sluggishness of movement in the right pupil, and during the last week of life marked constipation. At no time was the pain severe enough to require opiates, and as antipyrine and other remedies and the ice bag had been tried without any effect, and as I believed the ear was the cause of his symptoms, no internal medication was used except calomel for the constipation.

Twenty-four hours before death he became mildly delirious, then occasionally screamed out as from sharp pain, became unconscious, and within an hour afterwards died quietly. The most continuous pain and most frequent vomiting occurred during those days when the pulse was lowest. The temperature was normal throughout; the pulse varied from 85 to 52.

The autopsy by Dr. Gannett reads as follows:—

"Body small and emaciated. Convulsions of brain markedly flattened; pia dry; dura covering the vertical part of the petrous portion of right temporal, over an area of the size of a five cent nickel surrounding the foramen for the seventh nerve, was thickened and opaque, and of a yellow color, and adherent to the pia of the right half of the cerebellum, corresponding to this position. In the cerebellum, corresponding with this part, was a cavity, size of an English walnut, with smooth walls, and filled with a greenish, very offensive pus. The remaining portions of brain showed nothing remarkable.

"On removal of the right tympanum the tympanic cavity was found to contain in one portion, a reddish tissue, which was adherent to the walls. Just behind the tympanum was a cavity in the bone, size of a filbert, one part of the bony wall of which was carious, and adherent to the inflamed portion of the dura already described. The trabeculae of the mastoid cells had in great part disappeared, the cavity containing a soft, grayish, cheesy material with a foul odor.

"The organs of the thorax and abdomen showed no appearances worthy of special notice.

"Diagnosis: acute, circumscribed internal and external pachymeningitis; acute, circumscribed septo-meningitis; abscess of the cerebellum; flattening of the convolutions of the brain; dryness of pia; chronic middle-ear catarrh; necrosis of the mastoid cells, and of the petrous portion of the temporal bone."

In view of recent successful operations on brain-abscesses, the case is of interest. The diagnosis in this case cannot be said to have been fully determined, although abscess of the brain seemed most probable from the long continuance of the otorrhoea and the existence of caries in the tympanum, conditions which are among the most common causes of brain-abscess, and also by exclusion of all symptoms pointing to meningitis or disease of the sinuses. All localizing symptoms were, however, entirely wanting; facial paralysis is such a common symptom accompanying inflammation of the tympanum, especially caries of that cavity, which was found at the time of operation in this case, that it was of no value in settling the seat of the brain-disease. The patient himself always referred his pain to the parietal and temporal regions, and the only possible localization of the abscess was by probability from our knowledge of pathology.

If the exact condition of the petrous bone, and the fact that the posterior surface of that bone was carious, could have been determined, the cerebellum would have been suspected to be the seat of the disease, for it is quite well established that, in most cases, disease of the posterior surface of the petrous bone is associated with abscess of the cerebellum, and disease of the upper surface of the petrous bone with abscess of the cerebrum. Disease of the upper surface of the bone is, however, much more common than disease of the posterior surface, and this, combined with the fact that in this case the patient referred to the parietal and temporal regions as the seat of pain, would have led me to expect abscess of the cerebrum, rather than the cerebellum.

Vertigo is found in both cerebellar and cerebral disease, although more common and more severe in cerebellar disease; it was a prominent symptom in this case, but it is also very common from any tympanic condition which produces intra-labyrinthine pressure, and here not only was the tympanum filled with the stumps of the polypi, which might easily produce labyrinthine pressure, but syringing of the meatus always produced a certain amount of dizziness, even when very gently done.

Anatomically, the bone affords an instance of a very unusual place for caries to penetrate the cranial cavity. An extension of caries to the posterior aspect of the petrous bone commonly occurs along the internal auditory meatus, the aqueductus vestibuli, or the petrosomastoid canal, all of which furnish direct communication from the labyrinth or mastoid to the posterior surface of the bone. In this case, however, the carious opening, about 10 mm. in diameter, was midway between the lateral sinus and the opening of the aqueductus vestibuli, and was undoubtedly an extension from the mastoid-antrum directly backwards. The freedom of the labyrinth from inflammation was established during life by the fact that the tuning-fork on the forehead was heard entirely in the diseased ear.

Clinically, the case affords another demonstration of the slight symptoms often found with brain-abscess, and also of the insidious way extensive disease of the

bone may go on without offering any symptom externally, except an otorrhea.

The possibility of evacuating, draining, and healing an abscess of the cerebellum has not, I believe, yet been demonstrated, although a number of successful operations on the cerebrum have been reported. The cerebellar operation offers unusual difficulties in that it is either necessary to enter the skull below the superior curved line of the occiput in order to avoid the large sinuses, or else to pass through the tentorium from above, with the risk of imperfect drainage.

Hospital Practice and Clinical Memoranda.

CASE AND CONTENTS FOR USE IN RENDERING FIRST AID TO THE INJURED ON THE FIELD OF BATTLE.

BY W. THORNTON PARKER, M.D., NEWPORT, R. I.
Late Acting Assistant Surgeon, United States Army; member of the
St. John's Ambulance Association, England.

In the "Reference Hand-Book of the Medical Sciences," (p. 722, Vol. III) is to be found an article by Surgeon Woodhull, U. S. A., describing a Soldier's and Sailor's Clothing-Case invented by me in 1885.

The case is made of light canvas or waterproof cloth, and when completed it weighs but a fraction of the weight of the average knapsack. It is manufactured as follows:

A strip of cloth four feet long, or four feet six inches is a better length, by sixteen inches wide, is folded to make a pocket six or eight inches deep. This is done by making the covering flap lengthwise and dividing it into three pockets by a few stitches across at a third of its length, making three equal divisions. Six buttons hold the flap in place. Loops at either end enable the soldier to wear it secured at the ends without it being rolled in blanket or overcoat. This case will hold two pairs of drawers, two flannel shirts, two pairs of stockings, towels and other extra pieces of clothing, and the "soldier's book."

It is useful in that it can be worn for days without giving fatigue, and the weight is so evenly distributed that the soldier does not suffer from carrying it or feel disposed to throw it away. Upon reaching camp the blanket can be unrolled and the case hung up or thrown in the corner, the clothing remaining in the case clean and undisturbed. The case will be found useful as a pillow when folded. When the clothing is rolled loosely in the blanket only, upon reaching camp the blanket is needed and the contents are likely to be scattered about the tent and soiled or ruined with mud and rain.

This clothing-case does away with the necessity of knapsack or clothing-bag, and can be manufactured easily and quickly, and at a trifling expense compared with the cost for the manufacture of knapsacks. The expense saved by the use of this case would be very great indeed in the equipment of even one regiment. No clothing-case could be more easily carried than one suspended from the shoulder. It can be used at

all times, even in action, and would then offer considerable protection of the vital organs against musket balls.

It is intended that this case be worn in the rolled blanket suspended from the left shoulder, giving the right arm full play and allowing, as we have seen, the utmost freedom in the performance of the most important exercises of the manual of arms.¹

Such is the description of the case as originally invented for the use of the soldiers and sailors in general. In preparing a work on "Military First Aid to the Injured, and Stretcher and Ambulance Drill," it has occurred to me that for Red-Cross Sergeants on the field no better case could be devised for carrying the necessary instruments and appliances to be used in first aid. The knapsacks, bags, and haversacks in use in the hospital corps of the European and American armies are clumsy and very tiresome. The constant stooping and rising positions assumed by the medical attendants in ministering to the sick are made doubly irksome by the clumsy and heavy bags and haversacks suspended by a strap which often cuts deeply into the shoulder of the wearer. I have devised a case for a Red-Cross Sergeant made in the same fashion but of different material than that used by the soldiers and sailors, who wear theirs inside the rolled blanket. This case is to be made of brown waterproof cloth secured at the right side by two strong straps. When required for use it can be quickly unslung and opened and as quickly closed and slung into position again.

The contents are as follows:

One Hypodermic needle and rubber-stoppered bottle containing Magendie's solution, morphia. (Tiemann & Co.); one-half pound Lawton's absorbent cotton in a flat package; six woven bandages, antiseptic, (Tiemann & Co.); six first aid triangular bandages, (Tiemann & Co.); one case isinglass plaster; one inch tape; one package in flat wooden box, surgeon's adhesive plaster; three sponges in waterproof bag; two tourniquets, field (Tiemann & Co.); two tourniquets, Esmarch, (Tiemann & Co.); one tin box wax candles and matches, and folding lantern; one Red-Cross Sergeant's dressing case, (Tiemann & Co.)

This case will be found of great practical convenience and can be furnished at reasonable expense and much below the cost of Hospital knapsack bags, and haversacks already in use.

A very good field stretcher can be formed at once with three of these cases, either full or empty, secured upon two rifles. The ends of the cases being folded over the rifle stocks, and secured beneath. Number one holding the butts of the rifles as he would hold the stretcher handles, and number three holding the muzzles.

TWO CASES OF CANCER.

BY H. H. A. BEACH, M.D.,
Visiting Surgeon, Massachusetts General Hospital.

CARCINOMA OF LEFT BREAST: A NEW AND EFFICIENT MATERIAL FOR DRAINAGE TUBES.

A WOMAN, fifty years old, in good health, has noticed a lump in left breast for some ten months. Skin adherent over tumor, which is movable on the parts beneath. A few glands, the size of beans, felt in the axilla. Operation done; removal of whole breast, with a dissection of the axilla. Previous to

¹ Read before the Boston Society for Medical Improvement, April 23, 1888.

² Journal of the American Medical Association, March 6, 1886.

the operation, for several days, breast and axilla, whole side of chest, and inner side of arm were scrubbed with a nail-brush and a solution of phenyle ($\frac{1}{20}$), and then with corrosive sublimate ($\frac{1}{1000}$), the axilla being shaved clean before the scrubbing. Boiled silk sutures, kept in strong alcohol and soaked in corrosive sublimate just before the operation, were used, and juniper oil catgut ligatures for a few bleeding vessels. The drainage was maintained by means of quills at either end of the incision.

The first and only dressing was done seven days after the operation, and the wound found healed solidly. The stitches were removed, together with the drains. It was found that the tubes had remained patent, clean, and unclogged by discharge of blood or serum. The tube-holes remaining were small, and seemed to heal quicker than the opening from which a rubber drain was removed in a breast case done the same day. The tube allowed of greater firmness in the application of the dressing, resisting compression more successfully than rubber tubing.

The patient was discharged from the Hospital at the end of fourteen days.

[NOTE.—The object of reporting so common a case as cancer of the breast was to record the use of a new and valuable means of drainage applicable to all cases where rubber tubes are used.]

CANCER OF THE PYLORUS, WITH GREAT DILATATION OF THE STOMACH.

The patient, a woman thirty-seven years old, had excellent health up to within one year. Since that time has lost flesh and strength, has vomited considerably, especially after meals. Has vomited no blood of bright color. Vomitus coffee-ground, mucus-like

material. Has noticed swelling of abdomen for two months. Bowels constipated; no cough. She was pale and extremely emaciated. Abdomen distended unequally, more on the left than on the right side, presenting a tumor that extends from beneath the left costal cartilages down on left side of abdomen, and across below umbilicus to right iliac fossa, where a

hard mass can be felt about the size of a fist, which is slightly movable and flat to percussion.

The patient was unable to take much nourishment, and failed rapidly. Eight days after entrance, temperature subnormal: only once above normal.

Reports of Societies.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.

CHARLES P. STRONG, M.D., SECRETARY.

MEETING December 5, 1887. DR. C. F. FOLSOM in the chair.

DR. H. E. MARION read a paper upon

A CASE OF PYO-PNEUMOTHORAX, WITH AUTOPSY, IN A SUBJECT WITH EXTREME RETRO-LATERAL CURVATURE OF THE SPINE.¹

DR. A. N. BLODGETT read a paper entitled

TWELVE YEARS IN THE DEVELOPMENT OF A CASE OF MORAL IMBECILITY.²

DR. HENRY I. BOWDITCH said that the case was a painfully interesting and very important one. He thought that a grave responsibility rested upon all persons actually cognizant of the facts in regard to the questions of allowing such a patient to be at large in any community. The youth might kill any one present at this meeting but no jury would ever convict the assassin of murder, after hearing the details of his life and gradual development in normal obliquity, given by the reader.

DR. FOLSOM, spoke of the case of the notorious Jesse Pomeroy and said that the latter case was not one of moral imbecility. At the time of Pomeroy's sentence to be hanged only one definite diagnosis of the disease was made, namely, marked epilepsy, which, however, has not been justified by the subsequent history of the case. Pomeroy had no striking mental or moral defect or perversion except a love of torturing primarily, animals, and later children, for the gratification which their suffering gave him. The case was, in his opinion, similar to that of Piper, who had intercourse with dead or dying women, and to those of others who had intercourse with young girls or mutilated women for the added sexual gratification produced by the contortions induced by the sufferings of their victims. The cases were not many in which this striking perversion of character could properly be said to so far exceed the limits of self-control as to amount to real moral insanity or strictly speaking, one of its divisions, namely, *folie impulsive*. Dr. Folsom considered the Pomeroy and the Piper cases both in the same category and as not constituting real insanity or involving irresponsibility. At all events, there was no moral imbecility in either case.

In regard to the case reported by the reader, Pinel has remarked, and his observation had been verified by subsequent experience, that striking moral perversion had not the same significance in children and youths as in adults and that age and proper discipline often corrected it, while if neglected or treated with weakness and indecision, it developed into actual moral insanity or primary insanity, so called. Dr.

¹ See page 544 of the Journal.

² See page 537 of the Journal.

Folsom thought that the responsibility of allowing such a boy to go at large was very grave. If he were definitely insane, he should long ago have been confined in an insane asylum; if not, then sufficient control and discipline should have been exercised in another way, if need be in an institution of another kind, so as to protect the community and himself against his uncontrolled evil ideas or impulses.

BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.¹

F. B. HARRINGTON, M.D., SECRETARY.

DR. F. H. WATSON presented a specimen, and said: I have an unusually perfect specimen of tumor of the bladder, which I removed from a patient, a male, thirty-seven, yesterday morning. It is so rare to get this papilloma of the bladder in anything like perfect form that I thought it worth while to show. The tumor was situated above the right lobe of the prostate, and between that and the right ureter. It grew from a pedicle about the width and thickness of the thumb, which was perhaps a quarter of an inch long. The surface of the tumor which was exposed above the pedicle was the size of a small Tangerine orange, the larger portion of which is shown in this first piece which was removed at once. The rest was removed in a fragmentary way, and is shown in this second bottle. Microscopically, it shows a very fine specimen of the villous formation which occurs in these growths. There was no reason to suppose that it was anything but a benign papilloma. It is too soon, of course, to predict anything about the result. Under the microscope, with a low power, I have placed a piece of the growth which shows the villi very well indeed. There was no pain or bladder symptoms.

DR. FITZ: Had any of the villi been removed by the use of the endoscope?

DR. WATSON: The endoscope was not used, because the growth was so vascular that the bladder was filled with clots all the time. The amount was larger than in any case that I have seen that had not been disturbed. And it was not necessary to use the endoscope, because the characteristic bits of villi came away in almost every specimen of urine passed.

DR. BEACH: I have a patient to present to the Society. It is a case of simple amputation of the breast with removal of the glands of the axilla. The interest lies in the matter of drainage, which was by the use of quills. The patient entered the hospital on the first of April, and was discharged on the fourteenth. She had one dressing, eight days after the operation, and the union was absolutely by first intention.²

DR. J. O. GREEN reported

A CASE OF ABSCESS OF THE BRAIN FROM EAR DISEASE.³

DR. JOHN HOMANS showed a cartilaginous sarcoma of the femur, for which he had amputated the thigh. The patient was twenty-five years old.

DR. BEACH reported the case of a patient who entered the Hospital for operative interference for cancer of the pylorus. She was almost mori-

bund when she entered, constantly vomiting, and from the size of the tumor it was fair to infer that secondary deposits had been formed; as was afterward proved at the autopsy.⁴ Dr. Fitz has kindly consented to show the specimen, and I have asked Dr. Newell, who was present and assisted Prof. Bilroth in one of his operations, to show some of the plates illustrating the subject.

DR. FITZ: I was not at the autopsy, but saw the specimen while still distended. It is now smaller than in the original condition. The deformity of the stomach is very well shown in the photograph. It has evidently taken place mainly along the greater curvature. The smaller curvature is not much increased in length. The cause of the distension was evidently to be found at the pylorus, where there was a cancerous stricture, not admitting the tip of the little finger. The disease was located mainly at that point, but along the smaller curvature, in the immediate vicinity of the strictured portion, an enlarged lymph-gland, evidently cancerous, was found, and there were others in the immediate vicinity or behind the stomach. The interest of the case, apart from the enormous distension of the stomach, of course lies in the possibility, in an earlier history of the case, of removing the strictured portion. It seems as if this might have been a good case, if any case of the disease ever is.

DR. O. K. NEWELL: This stomach shows very nicely the way in which the malignant growths of the alimentary canal tend to remain local for a long time. It exemplifies that fact except for the enlarged glands; the growth itself has sharply defined borders. I thought it might be interesting to show the plates of Bilroth's operations. What Dr. Fitz has said about the lesser curvature not having changed, reminds one of what Nussbaum says in regard to the fact that all wounds of the greater curvature are dangerous on account of hæmorrhage.

DR. JOHN HOMANS: I have once seen, after laparotomy, some weeks after, a great distension of the stomach. It seemed to me to be caused by a sort of atony of the bowels. There was no peritonitis, but, on opening the abdomen, after death, the stomach appeared to fill the whole abdominal cavity. There was nothing to be seen but the stomach; none of the intestines. That was the only time that I ever saw the normal stomach so distended. It contained, I think, eight quarts of fluid, and, of course, considerable gas.

DR. FOLSOM: I have two very remarkable composite photographs by Dr. Noyes, of the Bloomingdale Asylum, New York, which I will show. Eight cases of melancholia, and eight cases of general paralysis. I think that either photograph would be sufficient to establish the diagnosis.

DR. F. B. HARRINGTON said: I would like to show some fragments of the temporal bone removed after a compound fracture. A brakeman struck a low bridge, and was brought into the hospital. I saw him about four hours afterward. He was conscious, though stupid; the pupils were normal; there was no paralysis. The injury was to the forehead. There was a small opening through which blood was oozing; there was considerable puffiness, and there was evidently fracture of the bone. It seemed best to enlarge the opening, and this was done. These six large pieces, with smaller ones,

¹ Concluded from page 528.

² See page 546 of the Journal.

³ See page 518 of the Journal.

⁴ See page 519 of the Journal.

were removed. One piece includes a portion of the orbit and the frontal sinus, and considerable bone above. None of these pieces were replaced, because there was considerable oozing, and it seemed wiser to make the effort to stop that and keep the wound as sweet as possible. Therefore it was packed with iodoform gauze, and the man has done exceedingly well. For a few days he had to have the straightjacket, on account of restlessness and not on account of maniacal symptoms. He is now doing very well indeed, twelve days after the accident.

Dr. BEACH: I saw him to-day, and found him sitting up in bed.

SURGICAL SECTION.

FIRST DAY, TUESDAY, MAY 8TH.¹

THE CÆCUM AND APPENDIX; THEIR RELATIONS IN HEALTH AND DISEASE.

By JOSEPH RANSOHOFF, Cincinnati.

The appendix maintains a pretty regular position in its relation to the cæcum; in most cases it lies behind the latter, and does not project forward. The appendix is supplied with a mesentery, a branch of the peritoneum, which connects it with the cæcum, the last two inches being free and unattached. The fact that the appendix is covered with peritoneum limits the danger of perforation and abscess, on account of the natural tendency of inflamed peritoneal surfaces to adhere. Anatomical peculiarities help us to explain the difference in symptoms of inflammation of this part. If the cæcum be inflamed, the tumor will present in front, if the inflammation is in the appendix it will not be so apparent. Rectal exploration may assist in the diagnosis of the latter condition. The fact that the appendix lies so near the ilium would explain the existence of symptoms of constriction when there is inflammation in this locality. The essayist was impressed with the presence of folds of mucous membrane in the cæcum, which are obliterated, when it is distended, thus favoring the escape of fecal matter into the appendix. It may be concluded that its function is similar to that of the cæcum. As to varieties of inflammation, it may be understood that disease of the appendix is much more frequent, especially in serious cases, than that of the cæcum. Perforation of the cæcum, which is quite rare, may be caused by fecal pressure, or by the presence of foreign bodies. It is, therefore, unreasonable to ascribe all perforations in this region to the appendix alone, although, in the large majority of cases, it alone is at fault. In some cases, owing to a lack of blood supply to the tip of the appendix, it, the tip, will be found gangrenous in the midst of an abscess. This gangrenous portion involves only the tip, while, if any perforation exist, it will usually be found near the cæcal attachment.

What more probable than that an abscess in this region should work its way to the surface, either above or below Poupart's ligament, or should follow the line of an umbilical hernia, as in a case observed by him?

A CASE OF TYPHILITIS AND PERFORATION; LAPAROTOMY; RECOVERY.

By L. S. McMURTRY, Danville, Ky.

Dr. McMurtry was called to see a case in Somerset, Kentucky, on January 26, 1888, with Dr. Perkins, who had been in attendance. The following history was obtained:

The patient, who was a young physician, had been subject to short attacks of colic, accompanied by nausea and vomiting, with pain in the iliac region. There was marked dullness on percussion, and on palpation an induration was perceived over the line of the ureter, giving the impression of obstruction of that duct. Later the swelling of the iliac region increased. Morphia had been used, and laxatives administered to relieve constipation.

When Dr. McMurtry saw the case he recognized a tumor of the caecum coli, and an operation was decided on. An incision was made over the median line, when it was found that there was no general peritonitis. The cæcum was drawn to the opening, and the vermiform appendage found normal. Two perforations, as large as silver quarters, on the anterior surface of the cæcum allowed the contents of the gut to escape. These were made elliptical in shape, and closed with silk sutures. The diseased parts were cleansed, a rubber drainage-tube was introduced and the wound closed with silk. The bowels were evacuated on the third day, and convalescence proceeded without the temperature rising above 100°, so that on the fourteenth day the drainage-tube was removed. Opium was used very sparingly.

The reader could find on record only one case of laparotomy for perforation of the cæcum, that done by Regnier in 1886, which terminated fatally. He, therefore, believes his case to be unique.

DISCUSSION.

Dr. EDMUND ANDREWS, Chicago: The important point to know in these cases is when to make a laparotomy. The risks of the operation will not allow the flippant statement that it can be performed with impunity, the dangers seeming to be greater than in ovariectomy. The surroundings for operation are usually not so favorable. If we are certain that an abscess has ruptured into the peritoneal cavity, laparotomy offers the best chances; but he is sure from his own experience that the patient may have some chance of recovery from perforation of this viscus even if laparotomy be not performed.

Dr. S. W. GROSS, Philadelphia: There are certainly a large number of cases of retro-peritoneal abscess that open posteriorly, which do not demand laparotomy; but there are a larger number, in which perforation of some part of the intestine occurs, which will be benefited by operating. For instance, where there is perforation in a case of walking typhoid, laparotomy would be justifiable. If we delay in these cases death is almost inevitable, but we may save some lives by prompt operation.

Dr. NELSON, Connecticut, related a case with iliac pain, obstruction of the bowels, and evidence of abscess, which later pointed in the iliac region. He introduced an exploratory needle, removed the pus, and the patient recovered. He hesitates to perform an operation of such gravity as laparotomy in these cases.

Dr. S. W. WEEKS, Portland, Maine: As to the point of incision for laparotomy, his experience has convinced him that the incision made over the cæcum is preferable to one in the median line. He has found

¹Continued from page 531.

the appendix to be beneath a point one inch above and one inch to the inner side of the anterior superior spinous process of the ilium.

DR. LEE, Philadelphia: With an extravasation into cellular tissue around the cæcum, accompanied by severe pain, we have the indications that laparotomy is required.

In a case of his own he had observed an abscess opening in the inguinal region, through which escaped a lumbricoid worm. The case recovered. The practical question to be considered is this, Shall we interfere after suppurative inflammation is established, or before it occurs in this region? His own experience does not satisfy him that a laparotomy in most cases gives the patient increased chances of recovery.

DR. MOORE, Rochester, N. Y. Is it not the rule that if sufficient local treatment be used almost all cases will recover without operation? In these cases of localized inflammation, we are very apt to find phantom tremor, and we may do our patients inestimable harm by too hasty operative interference.

SECOND DAY.—WEDNESDAY, MAY 9.

INTESTINAL OBSTRUCTION IN ITS SURGICAL ASPECTS,

by CHARLES BINGHAM PENROSE, M.D., of Philadelphia.

Early diagnosis is, in these cases, so important that he advocates an early exploratory laparotomy. Enterotomy and colotomy are not advisable as primary, though they may be performed as secondary operations after laparotomy. He considers a median operation more practicable than one over the region of the obstruction, for the tumor, if one is present, does not always represent the seat of the trouble. Incision of the intestine for the relief of distension is better than puncture, for the reason that the opening made by the former can be accurately closed, while the punctured wound is liable to leak. To find the seat of obstruction, the distended portion of the gut should be followed towards the rectum, the pelvis, or the most congested parts. The intestine should not be drawn through the cut, unless the distension is very great, but manipulation should be carried on as much as possible within the abdomen. Any constriction or opening that has trapped the intestine should be closed before ending the operation.

In cases of obstruction from any malignant disease, an artificial anus may be made and the cancerous mass removed at once. A temporary anus may be made, even as high up as the jejunum, both ends can then be united to the wound, and previously prepared food be administered by this new opening, as well as by the mouth. The abdomen should not be closed until the intestine has been emptied of air through an incision which can be closed subsequently, for the distension tends to produce kinks and strangulation.

If the symptoms of obstruction continue after the operation, the wound may be reopened and an artificial anus made. The wound is closed antiseptically after the operation.

The essayist dwelt upon the value of irrigation of the peritoneal cavity whenever the symptoms indicate the onset of inflammation or septic disturbance.

RECTAL INSUFFLATION WITH HYDROGEN GAS AS AN INFALLIBLE DIAGNOSTIC MEASURE IN ASCERTAINING THE EXISTENCE OF VISCERAL INJURY OF THE GASTRO-INTESTINAL CANAL IN PENETRATING WOUNDS OF THE ABDOMEN, ILLUSTRATED BY THREE EXPERIMENTS,

by N. SENN, M.D., Milwaukee, Wisconsin.

A perforating wound of the stomach or intestine must be looked upon as fatal, unless treated by laparotomy and closed. The difference between penetrating wounds made by stabs and those made by bullets has been recognized by all practical surgeons, for the prognosis in the former is much more favorable than in the latter. The medico-legal importance of this subject is very great, as it is not easy to decide in many of these cases whether an individual who has been shot has succumbed to the injury produced by the gun-shot wound, or to the operation necessary to determine that the alimentary canal has been perforated. Therefore, if we can possess some infallible means of diagnosing the existence of a perforated intestine, so that it will not be necessary to endanger the patient by handling over the whole intestinal tract, we shall be able to hold out a more favorable prognosis, and also in cases of medico-legal importance, to give positive testimony.

His numerous experiments on the subject have proven conclusively that the ileo-cæcal valve will not allow fluids, even under a high pressure, to pass from the cæcum into the ileum; but recent experiments made by inflating the larger bowel with gas have proven that by this means the valve (ileo-cæcal) is rendered incompetent, and the whole intestinal tract, and even the stomach, becomes distended with the gas employed. He found in these experiments that hydrogen gas gave more positive results, because it is innocuous to the system, and its presence could be demonstrated more easily than atmospheric air.

Experiment No. 1 illustrated this principle. An anesthetized dog was placed on the table, and a tube was introduced into the stomach. Within thirty seconds after inflating the bowel with hydrogen, the gas escaped from the stomach-tube and was ignited. It is necessary in this experiment to introduce a stomach-tube to overcome the constriction of the cardiac orifice, which always exists when the stomach is distended.

As to the pressure required to render the ileo-cæcal valve incompetent, his experiments with the manometer showed that it varied between *one-fourth pound* and *two pounds*, and was actually less when the subject was a man than when it was a dog. Furthermore, the pressure should be gradual, uninterrupted, and continuous to effect the result.

He has found that the pyloric orifice of the stomach acts toward gases very much as the ileo-cæcal valve does towards fluids, and effectually prevents the escape of gases from the *stomach* into the intestines, even although great force be used.

Experiment II demonstrated that hydrogen gas will escape through an opening in the intestine, and so through an opening in the abdominal wall. An abdominal section was made on a dog, and a minute incision made in the convex surface of a fold of the intestines, which were then replaced and the incision in the abdominal wall closed. A glass tube introduced through this latter incision allowed the escape of the

gas when the rectum was inflated. No gas escaped by the mouth.

Experiment III. Dog was shot in the abdomen with a 32-calibre revolver. The gut was then inflated with the hydrogen gas, a glass tube introduced into the gun-shot wound in the abdominal wall, and in a few seconds the escaping gas was ignited at the mouth of the tube. On opening the abdomen, the jejunum was found perforated in three places.

In summarizing his paper, which was too voluminous to be read in full, the essayist stated :

(1) That the entire alimentary canal is permeable to gases introduced with sufficient pressure into the rectum.

(2) That insuflation of the canal from the mouth is impossible because, although the stomach may be distended, the pyloric orifice will not allow the gas to pour into the intestine.

(3) A pressure of from one-fourth pound to two pounds is necessary to inflate the intestinal canal so that the gas will appear at the mouth.

(4) Resisting power is the same in all parts of the canal.

(5) The insuflation should be practised with a slow and continuous current.

(6) Hydrogen gas is preferable, for the reason that its presence can be demonstrated so readily.

(7) Hydrogen is not toxic, is innocuous to all the tissue of the body, and is rapidly absorbed, so that in from twelve to twenty-four hours after the experiment no trace of it can be found. These statements he has proven by injecting with this gas the alimentary tract, the peritoneal and thoracic cavities and cellular tissues, and in no instance finding any harmful effects follow.

(8) The escape of the gas through the ileo-cæcal valve can be distinctly perceived by placing the ear over the abdominal iliac region, where a gurgling, hissing noise can be distinctly heard.

(9) In gun-shot wounds of the intestine, the surgeon, by means of insuflation of hydrogen gas, can not only determine the existence of perforation of the intestines, but, on opening the abdominal cavity, can easily find the point of perforation without searching over the whole intestinal tract. This is of inestimable advantage, for it eliminates to a certain extent the danger which arises from prolonged manipulation of these peritoneal surfaces.

All the coils of intestine below, that is, to the rectal side of the first point of perforation, will be distended with gas, while those above it will be collapsed. As soon as the perforation is closed, the examination can proceed upwards until all the wounds are closed.

On account of the lateness of the hour, the discussion was postponed until Thursday, May 10th.

SOME OBSCURE AFFECTIONS OF THE SIGMOID FLEXURE,

by JOSEPH M. MATHEWS, Louisville, Ky.

He has given special attention to diseases of the rectum for some years, and offers some observations from his individual experience in the treatment of 2,000 cases of hæmorrhoids. He considers constipation to be the chief cause of piles, and cannot think that the distribution and course of the veins can initiate them. He believes them to be veritable tumors, in the formation of which the arteries play as important a part as the veins. The congestion of the part allows the deposit of plastic inflammatory material. Of

all the methods that have been employed in operating on these cases ligation stands pre-eminent. Instead of dissecting the tumor, he passes a delicate knife around the base of the pile, simply going through the integument. He uses the strongest linen thread for a ligature, tying it in a simple hard knot as tightly as possible. Owing to the danger that may arise from the feces becoming impacted, he purges the patient on the day of the operation, and keeps the bowels open afterward, allowing a full diet.

If internal hæmorrhoids exist with no complication, he does not consider an anæsthetic necessary, nor has he found any benefit derived from the use of cocaine, excepting in the removal of external piles. Strict antisepsis is not possible in these cases, but cleanliness must be observed; and where cutting is done, iodiform should be dusted over the parts. Using these methods he has never had a death from the operation, and but few untoward symptoms have followed it.

A NEW METHOD OF FORCIBLE CORRECTION OF OLD SUBLUXATIONS OF THE TIBIA.

by E. H. BRADFORD, Boston.

Subluxations of the tibia in chronic disease of the knee-joint are caused by the spasmodic contraction of the ham-string muscles, pulling the tibia backward in a joint whose ligaments and capsule have been relaxed by disease.

This condition is not as common in the knee-joint affection of locomotor ataxia, as in strumous or tubercular arthritis. In the latter class of cases the contracted posterior wall of the capsule, as well as the contracted ham-string muscles prevent the reduction of the dislocation.

Neither raising the lower part of the tibia, nor simply pulling upon the leg will correct the deformity, for the strong posterior ligaments resist such force. In an experiment on a cadaver he had observed that the tibia could be pushed forward an inch, and, with considerable force the crucial ligaments could be torn and the post-ligaments considerably stretched.

These posterior ligaments and the posterior wall of the contracted capsule offer the only resistance in reduction of such a subluxation, for the crucial ligaments have usually been destroyed by the original disease. To overcome the resistance of these ligaments, he makes use of an apparatus by means of which he presses the head of the tibia forward by screw power, counter pressure being applied to the end of the femur. After reduction of the deformity the limb is held in the proper position by means of plaster-of-Paris bandages. The pain that follows this procedure is inconsiderable, and in a short time the patient is able to walk about with crutches. In two cases cited, in which caries of the knee-joint occurred early in life, subluxation followed after complete recovery from the disease. This deformity was treated according to the method described. The results were very satisfactory, and the patients are able to walk without support of any kind.

A discussion followed on the papers of Drs. Peirose and Senn.

DR. CONNER, Cincinnati: It is not such an easy matter to determine the nature and character of intestinal wounds. The matter of greatest importance is the determination of the difficulty itself and its location. For acute obstruction the old methods of waiting may be well enough in some cases, and we have

all seen apparently good results from morphia and rest, yet in most cases this is a dangerous course. We have also seen cases operated on recover, while many others, apparently relieved at first, subsequently die.

It is not an indifferent matter whether laparotomy is performed or not, for this is not such a safe procedure. Statistics are not reliable, for many fatal cases are never reported. However, acute obstruction that does not yield to other measures within a few hours should not be operated upon. In a case of his own, in which the operation was not permitted, the post-mortem showed that there was constriction at one point, which, had it been removed by resection of the part, might have given the patient a better chance for life.

DR. WEEKS, of Maine: Not every case of obstruction should be operated on, and a reasonable length of time, during which medical treatment should be pursued, should be allowed previous to operative interference. The point at which pain is most severe is not always directly over the site of the obstruction.

In one of his own cases a young man had severe pain (which appeared suddenly), in the right hypochondriac region. This was followed by nausea, vomiting and constipation, and all the evidences of obstruction. At the end of the fourth day the patient died, when the autopsy revealed a knuckle of bowel near the ileo-cæcal valve, constricted by a band of fibrous tissue. He thinks that an operation would have brought relief.

In another case, presenting similar symptoms, except that the patient was moribund when he first observed him. An operation revealed an obstruction caused by a constricting band. The patient died.

While we may wait a reasonable length of time, we must not wait until inflammation has been established, for no patient can rally after having been reduced by a peritonitis. The conditions that should prompt the surgeon to perform laparotomy are the same, in his opinion, as those that govern him in relieving a strangulated hernia. Pain, suddenly appearing, constipation, nausea, vomiting, an anxious expression and hicough are symptoms which should indicate the necessity for operative interference in these cases.

(To be continued.)

Recent Literature.

On the Wasting Diseases of Infants and Children. By EUSTACE SMITH, M.D., Fellow of the Royal College of Physicians; Physician to his Majesty, the King of the Belgians; Physician to the East London Children's Hospital, and to the City of London Hospital for Diseases of the Chest, Victoria Park. Fifth edition. Philadelphia: P. Blakiston, Son & Co., 1012 Walnut Street. 1888.

This well-known work of a well-known author needs no further review than has already appeared many times in the medical journals. The text of the previous edition has been carefully revised, and certain alterations and additions have increased the number of pages from three hundred and thirty-three to three hundred and fifty-three, but the general arrangement of the chapters remains the same and no new subjects are treated of.

THE IMPORTATION OF LEPROSY.

THE Washington correspondent of the *Boston Post* gives some very interesting extracts from a report to the State Department from the Consul-General at Honolulu. According to this report, many lepers are emigrating from the Sandwich Islands to this country to escape the fate which awaits them at home if their affliction is discovered. As is well known to medical men, the laws of the kingdom banish to the island of Molokai any one recognized as a leper, where, in the language of the report, "shut off from the rest of the world, he has to await his end. Men just entering upon life, nobles of high rank, women of queenly beauty, are doomed to banishment the moment the copper-colored spots begin to appear." These words of the report differ widely from the language a medical man would adopt in speaking of the attempt to circumscribe the disease, but they serve very forcibly to show the feelings of many of those who suffer from the law either in their own persons or in those of their friends.

Accordingly, we are not surprised to be informed that some individuals make haste to escape before their condition is known, and they find a safe and most accessible refuge in California. Mr. Putnam, the Consul-General, finds it impossible to give statistics, but he believes the number of such refugees to be very considerable.

Starting as is this statement, it is not surprising. It is, however, far from pleasant to think that we are practically powerless against such an immigration; that even this eastern portion of the country is not too far removed to be reached by these exiles, has been demonstrated by the case at Salem a few years ago.

This matter is one clearly beyond the jurisdiction of State Boards of Health. If it is possible to control at all such undesirable immigration, it can be done only by the general government. If control is impossible, it is certainly possible to collect and disseminate information on the subject, and an evil which is known and understood is certainly less to be dreaded than one that worketh in secret.

THE TRAMP, THE DEAD-BEAT, AND THE CRANK.

It is rather strange that there seems to be no word in the English language to describe that genus of ill-balanced persons, who, while not coming within the category of criminals or insane, are yet stragglers in the march of civilization and improvement. They comprise the tramp, the professional beggar, the chronic borrower, the man who does not pay his debts, the quack in medicine, the shyster in law. The genus is certainly common enough to merit a name. Differing widely from each other in many respects, these species yet have certain common attributes, one of which is a disposition to get out of the world a living without paying for it. While, as we have said, they are technically not criminals, they furnish a good recruiting ground for that great army. The tramp, leading a merely vegetative existence, insensitive to cold, wet, fatigue, filth, vermin, would rather ride under a dusty freight car or sleep in a pig-sty, than earn his car-fare or his lodging. Perhaps the closest actual approximation to Shakespeare's Caliban, he may, if debarred from his animal desire for food or other gratification, instantly commit an unpremeditated murder, with as little reluctance as he would manifest at having to do any other kind of work. So the dead-beat easily becomes the thief, the quack, the abortionist, the shyster, the embezzler.

With other individuals the intellectual nature shares with the moral in the lack of regulation. Here may perhaps be classed the drunkard, the spiritualist, and in general the widely distributed varieties of the crank. Whether the moral or the mental weakness predominates, depends on the make-up of the person, and perhaps on his environment. The materializing medium when she lays her wiles, as lately in New York, for the property of a rich but singularly gullible victim, has been led by favoring circumstances from the sphere of the mere adventuress to that of the swindler. While the Christian Scientist who sacrifices the lives of her daughter and grandchild upon a vagary, has her obliquity chiefly in the mental faculties.

The foregoing remarks have been in part suggested by a paper read recently before the New York Society of Medical Jurisprudence and State Medicine, by Austin Abbott, LL.D., called the "Physiology of the Rogue." The use of the word "rogue" to describe these offenders against the good order of society, illustrates better than anything else could the point we referred to in the beginning, that there is no word which at all expresses the thing. The writer approaches the study of criminal responsibility through what he calls the physiological rather than the pathological ground. That is, he seeks to study "the eccentric action of an undiseased organization" as shown in all these classes of morally ill-balanced persons, rather than the morbid action of the organization which has fully developed disease. The writer gives a rather interesting delineation

of some points in that physiology of some of these classes. The tramp is a being of diminished or incomplete nervous activities. The spinal and cerebral centres, like the nerves of sensation, are dull, depressed and sluggish. Hence the apathy to cold, exposure and other discomforts. The ganglionic nervous system functions well, and the individual has good circulation, respiration, appetite and digestion.

"His characteristic offences are those of a sturdy brute; he breaks fences, tramples down the meadow, rifles the pantry, assaults or frightens women, pollutes the path, and fouls the spring. There is no danger that he will commit forgery. His nervous forces are not adequate to the work of a counterfeiter. There is not life enough in his brain to carry him into the perpetration of a commercial fraud or even a confidence game. The crimes of ingenuity and skill he has no brain for. Crimes of passion are, with but occasional exceptions, above his sluggish level; and the exceptions are those which are committed when the vigorous wants of his vegetative functions impel him to an unusual effort, or a refusal to minister to them awakens an ill-will, which, in respect of intelligence, is only a few degrees above that of a vicious beast."

Mr. Mantalini has very little in common with Caliban, except his hatred of work. The "dead-beat" unlike the tramp, has his nerves of sensation and his perceptive faculties in full function. "His keen appreciation of all the pleasures of the senses — of epicurean delicacies, of perfumes, of the beauty of a *boutonnière*, and the bouquet of fine wines, the luxury of toilet soaps and new gloves, make a curious contrast to the stolid indifference which his brother the tramp manifests. He lives in the sensations which these and other such things afford. But they do not awaken in him the intelligence or the volitions necessary to come by them honestly. He has a mental sensitiveness which prevents him from helping himself to them by force as the tramp does. But he takes them by indirection. He has just mental capacity enough to contrive his way to self gratification through the effort to make himself agreeable and plausible, to borrow, to wheedle, to flatter, cozen, and cheat."

The crank is at a great disadvantage compared with the tramp in regard to the activity of the vegetative functions. He is not well-nourished; he is likely to be dyspeptic. Nor, on the other hand, is he as solicitous of his personal comfort as the Sybaritic dead-beat. He is not deterred in his supposed mission of philanthropy by summer's heat or winter's storm. The centre of his nervous activity (unlike both of his congeners) is in the brain, but the balance-wheel is somehow wanting. The crank does not live in bestiality like the tramp, nor in sensuousness like the dead-beat, but entirely in the world of ideas, without appropriate inhibitory restraint. His acts show usually intelligent desire and intelligent adaptation of means to end. This constitutes his great peril to the

community, as when he has been led by his own unchecked fancies, acting on and reacted upon by the equally unstable intelligences of his fellows, to such acts as those of the Chicago bomb-throwers. Yet as Mr. Abbot points out it seems to be true in general, that the characteristic desires of the crank and the means he devises "involve only such thoughts and feelings as are or may be common to the minds of many thinking men; but, nevertheless, they are such as the mind of one not a crank would discard at the first thought as inhibited by something beyond or collateral. Every thinking man probably has at times impracticable ideas, and his wisdom consists in part in the judgment by which he recognizes their impracticability or impropriety."

Perhaps, as our author suggests, the cerebral activity is confined to special centres and channels without the modifying influence which would come through the action of surrounding inhibitory centres. We might, perhaps, illustrate it by the violence in the action of a current of water sent through a narrow sluice-way, as compared with the force (slight it may be, but safe, at least, to the by-stander), if the same volume of water is turned over a meadow. The figure may serve further to illustrate the fact that crankiness is closely allied to power. The force of the narrow current need not indeed tear the mill-race to pieces, but it is only as the current is confined that it can furnish force enough for the accomplishment of useful work.

THE TREATMENT OF DENUDED SURFACES BY GRAFTS OF CHICKEN SKIN.

THE latest novelty in the grafting line is the treatment of large solutions of continuity in the human subject by bits of skin transplanted from the chicken. Redard communicates to the Société de Biologie an article commendatory of this new method. In one of his cases, almost the whole scalp in a child was destroyed by a burn. Grafts of chicken skin were practised for four months with gratifying success.

According to this writer, the skin, with a little cellular tissue, is taken from under the wings of young chickens. Little transparent bits, not exceeding from half a centimeter to a centimeter, are excised. These readily adhere to the part on which they are grafted, and are simply covered with iodoform gauze and charpie.

Redard regards chicken skin as the ideal grafting material, being supple, fine, and vascular. It spreads well and evenly over surfaces, and adheres without being absorbed, making epidermic islets which, in developing and spreading, form new tissues which are supple (unlike ordinary cicatricial tissue) and likely to be permanent.

Readers of the JOURNAL will recall other attempts to lay the animal kingdom under contribution, notably the use of frog skin, as mentioned in the last Surgical Report.

MEDICAL NOTES.

— In his speech on the Mills tariff bill, Mr. Fitch, of New York, read a letter from Dr. William Perry Northrup, pathologist to the New York Foundling Asylum, who stated that his Jena microscope, which had cost him \$94, cost him forty per cent. more to get out of the custom house; that an oil immersion lens, costing \$80 at the factory, had cost forty per cent. more at the custom house; that he had to pay forty per cent. duty on an expensive microscope, and twenty-five per cent. on Dr. Koch's report of the German cholera commission.

— It strikes one as rather odd that a medical man should speak with so much complacency as does one correspondent of the *Lancet*, of the utility and excellence of having a "refreshment bar" for the benefit of the patrons of a hospital out-patient department. This has been provided at the Wolverhampton Hospital, and the out-patients assure the attendant that a "long-felt want" has now been supplied. We commend the scheme to such teachers as have hitherto been disappointed in securing all the material they wish at their clinics. A free lunch counter may prove more of a drawing card for the too coy "patient-public" than even a new chromo to each corner.

A correspondent of the *N. Y. Medical Journal* writes that a hydrocephalic child was born to an ultra-prohibitionist father, who said to the doctor:

"What is the matter with my child?"

"Why, it has inherited its disease from you."

"What do you mean?"

"Why, it has water on the brain."

— Señor Joaquín Bueno, of Rio Janeiro, is, if press reports are correct, entitled to the distinction of having devised a horribly radical measure for dealing with the Indian question in that country. The plan adopted was to drive away the inhabitants of a village and in their absence to poison the wells, wine and provisions left behind. It is said that 3,800 Indians have been already destroyed with strychnia and some mercurial preparation, and that 5,000 more are doomed to the same fate.

— A lady from Denver writes to the *Western Druggist*, inquiring the formulas, as published by that journal, of "Warners Safe cure, Swifts Specific (S.S.S.), and Humbolds Extract of Bucoe."

In reply, the editors say: "While regretting our inability to furnish all the information desired, we reflect with some satisfaction that our correspondent will not thereby suffer for the means of cure, for her letter-head further announces that she is the 'WONDERFUL WOMAN, BORN WITH DOUBLE VEIL; SEVENTH DAUGHTER; BORN IN MID-OCEAN ON CHRISTMAS DAY; DEAD TRANCE CLAIRVOYANT; CAN TELL YOUR MOTHER'S NAME BEFORE MARRIAGE; CAN DESCRIBE YOUR FEELINGS, ACHES AND PAINS, IF SICK, FROM LOCK OF YOUR HAIR AND \$1; USUALLY GIVES FULL NAMES, DATES AND PLACES; SENDS FREE OF ALL COST HER WONDERFUL ZOPPO, SO YOU CAN

win the love of and marry any particular person. Get book with Particulars Free. Send for your Life, written in a Dead Trance; send lock of hair, and Ladies, \$1, Gents, \$5. Phenological Charts, \$1; Written Card Fortunes, \$1; Palm, or Hand Fortunes, 50 c. Cures the sick and trusts for final cure for final pay."

The curious part of it is that a clairvoyant possessing all these qualifications, should have any need of the assistance even of such important coadjutors as the trio mentioned.

—The following circumstance is reported in the *Indian Daily News* (Calcutta): "A number of snakes, principally cobras, were sent to Dr. Vincent Richards for experiment. Dr. Richards took out one of the cobras with the object of getting some of its poison in a watch glass which he had ready for the purpose. He held the snake in his right hand, and was moving his left hand in front of it, when the snake bit him severely on the forefinger of the left hand. Dr. Richards, fortunately for himself, preserved his presence of mind; he killed the snake, and with a knife laid the finger open to the bone above the wound, and applied permanganate of potash; he then applied a ligature to the finger and another to the forearm and drove off for medical advice. Dr. Macleod and Sir Benjamin Simpson reopened the wound and thoroughly cauterized it with nitric acid. Ordinary dressings were then put on. More than two months have passed since the accident, and Dr. Richards is doing well."

NEW YORK.

—The fourth annual meeting of the Fifth District Branch of the New York State Medical Association was held in Brooklyn, May 22d. At the morning session the President, Dr. Edwin Barnes, of Pleasant Plains, Dutchess County, delivered his annual address, a considerable portion of which was devoted to the treatment of diphtheria by means of cubes, which, given in the form of the fluid extract, has proved very successful in his hands in several epidemics. After the business affairs of the Branch had been disposed of, Dr. J. Lewis Smith, of New York, read a paper on "Diphtheria of the New-born and Sepsis of the New-born, as observed in the New York Infant Asylum and New York Foundling Asylum." The afternoon session was principally taken up with a discussion on Surgical Aid in the Treatment of Pulmonary Disease, which was opened by Dr. N. L. North, of Brooklyn, and continued by Drs. J. D. Bryant, C. A. Leale, Avery Segur, C. S. Wood, and others.

—Dr. Allan Macy Butler, a grandson of the late Dr. Willard Parker, died of peritonitis at the Roosevelt Hospital, where he was senior assistant physician, on the 21st of May. Dr. Butler was a graduate of St. Paul's School, Concord, Harvard University, and College of Physicians and Surgeons, New York, and was a physician of great promise. He was twenty-six years old.

Miscellaneous.

MEDICAL ADVERTISEMENTS AND THE RELIGIOUS PRESS.

THE following resolutions were adopted at the Thirtieth Annual Session of the State Medical Society of Arkansas, held at Fort Smith, April 25, 26 and 27, 1888, and ordered to be furnished to the American Medical Association, the medical and religious press, and to the State Medical Societies, soliciting their co-operation in bringing about a correction of these grievous and palpable errors:

Resolved, That the members of the State Medical Society of Arkansas have for years observed with pain and mortification the patronage given to charlatanism in all its multifarious aspects by the religious press of our country.

Resolved, further and most specifically, That the appearance in religious papers, ostensibly published for the inculcation of truth and morality, of serious homilies on prayer and praise side by side with cures for consumption, cancer, Bright's disease, and other incurable ailments, to which an editorial endorsement is often given, as well as secret preparations under the cloak of remedies for disease, but really intended for purposes of feticide, and other immoral uses, largely tends to shake the confidence of the profession of medicine in the integrity and purpose of the managers and editors of such journals.

Resolved, further, That it has been the well-known custom of the profession to render services gratuitously to clergymen, which we do not regret nor do we propose to recall, yet we must assert that the frequent occurrence of endorsements and recommendations of the clergy of peripatetic doctors and advertising charlatans has in many instances been the only reward of our gratuitous services.

Resolved, further, That we are aware that the editors of religious newspapers admit the painful situation in which these advertisements place them, and attempt to excuse themselves by saying that it is necessary to take these advertisements in order to obtain means to conduct their papers; but, in the language of orthodox theology we would say: "Put behind you that damnable doctrine that we must do evil that good may come."

Resolved, further, That, as a Society, we declare that the continued perpetration of the above offenses by some of the clergy and religious press brings harm to the bodies of their constituency, and damages materially their influence upon the thinking class of the medical profession.

Resolved, That the Secretary be instructed to furnish copies of these resolutions to the religious and medical press of the United States, to the American Medical Association, and to the State Medical Societies, soliciting their co-operation in bringing about a correction of these grievous and palpable errors.

GLASSBLOWERS' CRAMP.

M. PONCEP has made a communication to the Académie des Sciences upon the subject of a professional deformity of the hand to which he says attention has not heretofore been drawn. The deformity is by him described in the *Lancet*, as consisting in a permanent and very pronounced flexion of the fingers upon the

hand, which is more pronounced in the case of the third and fourth fingers than the other two, and leaves the thumb wholly unaffected. The inflexion occurs principally at the second joint, so that the second phalanx is fixed almost at right angles to the first, and it is attributable not to sclerosis of the skin or tightening of the deeper tissues, but to retraction of the flexors and tendons, and more particularly of the superficial flexor. At this diagnosis the author has arrived by a careful examination of the affected fingers, and he argues much from the circumstance that the malady is unaccompanied by pain. The distal joints are more or less deformed, with some tendency to subluxation, and the fingers are bent into a curve, and cannot be extended. The skin of the palmar surface is somewhat thicker, and more callous than is usual even with manual laborers. This deformity is known among glass-workers as *main en crochet* or *main fermée*. It supervenes after a short practice of the art of glassblowing, and increases progressively. It is further stated upon the authority of an expert (Mr. E. Rollet), that it attacks the majority of glassblowers, and is most marked in those who have been longest at the work. M. Poncet thinks that the deformity which he has described is due to the continuous application of the hand to the tube with which a glassblower manipulates his "metal." He stated that, during the eight hours a day through which such a man ordinarily works, his fingers are without intermission kept closed about this tube, and the constraint induces, even within a month, some difficulty in effecting complete extension. This difficulty becomes greater and greater as time runs on, until at last it develops into the crippled condition of the hand which he has described. Altogether, he says, the trade of the glassblower as pursued in France, is so unhealthy that the operatives who habitually take it up as young men are obliged to abandon it on attaining about thirty-five years of age, and do so with their hands permanently crippled in such a way as to render them useless for almost any other occupation.

THE DOCTOR'S BILL.

THE *New York Tribune*, in commenting on the extraordinary bill of \$143,000 for professional services recently presented against the estate of a late distinguished statesman and millionaire—that bill representing eight years' medical attendance—makes these remarks:

"We venture to suggest that the most remarkable, and for various reasons the most instructive, feature of this transaction is not the size of Dr. S.—'s bill, but the fact that he should have been allowed to give his services during eight years without any compensation. We all know that Mr. T.— loved the pleasures of procrastination with a love surpassing that of woman, but this was certainly a most surprising exhibition of his favorite weakness. To receive during so long a period, and at times to monopolize the attentions of a successful physician without paying for them, was an exceptional and exaggerated instance of a bad habit which is only too widespread." Mr. T.— did not sin alone in this matter, though he made a record which it would be hard to beat. His fellow-sinners, if they could be gathered together, would make a large, and, it might be said, a select company.

Almost any physician, we venture to assert, will confirm the statement that there is no bill which is so long neglected, or so often left unpaid altogether, as the doctor's bill; and this is true of those who find it easy to pay, as of those who find it hard. The grocer and butcher are settled with among the first, of necessity. The lawyer takes his toll, like the miller, out of the grist before it passes out of his hands. Even the tailor often gets his money before the doctor, for the man who wants to be presentable must keep up, at least, a reasonable rotation of new clothes, whereas there is no telling from a man's external appearance, or from the condition of his health, whether he has squared up accounts with his physician or not.

"There seems to be an unformulated theory that doctors and their wives and children can live on air, as the chameleon was once supposed to do. A certain class of people feel apparently that the philanthropic nature of the profession requires the doctor to be ready at all times to give up his time and skill with only the faintest hope of reward, if any at all, not troubling themselves to reflect that he can hardly settle his own debts so easily. The result is that no class of workers, except the clergy, give so large a proportion of their labor for nothing. This is so, partly because physicians are constantly doing good deeds of which the world hears nothing, not only tending the poor without charge, but even buying their medicine and food. There is no nobler record of unselfishness in our modern life than that of the medical profession. But it is also true in part because they are continually imposed upon. The result of all this is that it is a common thing, as every one knows, for a physician who has held a leading place in the profession, and who has popularly been supposed to be in receipt of a splendid income, and be solidly rich as well, to die poor, as the world finds to its great surprise."

"One of the remedies often proposed for this state of things is that the doctor should get his fee at every visit, as in England, or as specialists do from office patients here. There can be no doubt that the adoption of such a system would save the doctors a good many bad debts, but they might not find it an agreeable method of collection. The social position of the ordinary medical practitioner is not so good in England as here, and this fact may have something to do with his willingness to collect his money as he goes along. The American is likely to prefer the present system, with all its faults, for a certain reserve and delicacy he finds in it."

OBITUARY WILLIAM GODDARD, M.D.

Dr. William Goddard whose death occurred in Boston, May 27th, was the oldest living graduate of Harvard College, the only survivor of his class, and the oldest surviving graduate of Harvard Medical School. He was born in Portsmouth, N. H., April 22, 1796, where he practised medicine for a number of years. Dr. Goddard was in college during our last war with England, graduated in the class of 1815, and at the Medical School in 1820. His father was Hon. John Goddard, of Portsmouth; his grandfather was John Goddard, of Brookline, who was renowned in the history of those times, having had charge of the work of throwing up the fortifications at Dorchester Heights. His maternal grandfather was Rev. Samuel Langdon, D.D., who was president of Harvard College during the Revolutionary war, as well as chaplain of Washington's army while stationed at Cambridge. Dr. Goddard was much esteemed for his intelligence, integrity and Christian virtues, being liberal and progressive in all his views. He was a man of genial disposition, modest and retiring in his nature, respected and beloved by all who knew him. Two children, a son and a daughter, survive him.

Correspondence.

HOW MANY LIVING GENERATIONS?

BOSTON, May 26, 1888.

DEAR SIR,—Judging from your Kansas correspondence of May 12th, it seems to be interesting to the editor of the *Boston Medical and Surgical Journal*, as well as to its readers, to know about living generations in one family. I therefore offer you the following facts.

A lady, American, and a widow, consulted me when forty-eight years old. She was intending to be married a second time, and was only waiting for the confinement of her granddaughter, who expected her second baby in a few

weeks. My patient had been a widow since her seventeenth year. Her daughter, (the grandmother), thirty-three years of age, had also married when scarcely fifteen years of age, and was a widow since her nineteenth year; while the young woman for whose confinement they were waiting would be seventeen years and three months old when the second baby arrived.

Some months later, the newly-married great-grandmother again consulted me, complaining of her miserable condition of health, "change of life," etc. On examination I found her to be twelve weeks pregnant, and when she was forty-nine years and six months old, she gave birth to a large healthy boy.

Query: How many living generations does this make?

Very truly yours, M. E. ZAKRZEWSKA, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 19, 1888.

Deaths reported 2,086: under five years of age 748; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 356, consumption 303, acute lung diseases 245, diphtheria and croup 125, diarrheal diseases 60, scarlet fever 40, typhoid fever 34, measles 22, cerebro-spinal meningitis 17, erysipelas 14, malarial fever 13, small-pox 11, whooping-cough 9, puerperal fever 2. From typhoid fever, Philadelphia 15, New York five, Milwaukee and Nashville three each, Baltimore two, New Orleans, Washington, Lynn, Lawrence, Holyoke and Newton one each. From measles, New York eight, Washington, three, Philadelphia, Baltimore, Boston and Pittsburgh two each, New Orleans, Milwaukee and Brockton one each. From cerebro-spinal meningitis, New York six, Washington, Pittsburgh, Milwaukee, and Gloucester two each, New Orleans, Fall River and Taunton one each. From erysipelas, New York 10, Boston two, Pittsburgh and Lynn one each. From malarial fever, New York seven, New Orleans five, Nashville one. From small-pox, Philadelphia six, New York five. From whooping-cough, New York, Phila-

delphia and New Orleans, two each. Baltimore, Boston and Charleston one each. From puerperal fever, Baltimore and Milwaukee one each.

In the 18 cities and larger towns of Massachusetts, with an estimated population of 381,026, the total death-rate for the week was 20.51 against 19.61 and 23.43 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,273, for the week ending May 5th, the death-rate was 18.7. Deaths reported 3,367: infants under one year of age 775; acute diseases of the respiratory organs (London) 287, whooping-cough, 146, scarlet fever 45, diarrhoea 38, fevers 32, diphtheria 31, measles 25, small-pox (Sheffield eight, Bristol two, Oldham and Hull one each) twelve. The death-rates ranged from 12.7 in Portsmouth to 28.1 in Salford; Birmingham 18.6; Bradford 17.0; Hull 17.0; Leeds 18.7; Leicester 19.9; Liverpool 17.5; London 17.4; Manchester 27.6; Newcastle-on-Tyne 22.0; Nottingham 16.0; Sheffield 19.1. In Edinburgh 21.1; Glasgow 22.1; Dublin 21.7.

The meteorological record for the week ending May 19, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MAY 19, 1888, TO MAY 25, 1888.

SUTHERLAND, CHARLES, colonel and medical director. To inspect the medical department at St. Francis Barracks, Fla., Fort Barrancas, Fla., Mount Vernon Barracks, Ala., and Jackson Barracks, La. S. O. 100, Division of the Atlantic, May 19, 1888.

TOWN, F. L., major and surgeon, United States Army, post surgeon at the Post of San Antonio, Texas. Will take charge of the office of the medical director at these headquarters, and perform the duties of that officer during his absence on leave. S. O. 51, Department of Texas, May 11, 1888.

BROWN, HARVEY E., major and surgeon. Directed to continue on duty at Fort Barrancas, Fla., until further orders. S. O. 115, A. G. O., May 18, 1888.

KIMBALL, J. P., major and surgeon. Leave of absence extended two months. S. O. 117, A. G. O., May 31, 1888.

MC CREECH, GEORGE, captain and assistant surgeon. To accompany 7th Cavalry from Fort Meade, Dakota Territory, to Fort Riley, Kansas. From Fort Riley he will return to Fort Meade. S. O. 42, Department of Dakota, May 17, 1888.

WYETH, M. C., captain and assistant surgeon. Will be relieved from duty at Fort Barrancas, Fla., at the expiration of his present leave of absence, and will report in person to the commanding officer, Fort Huachuca, Ariz., for duty at that post. S. O. 115, A. G. O., May 18, 1888.

KNEEDLER, WM. L., first lieutenant and assistant surgeon. Will accompany from Fort Snelling, Minn., that portion of the 25th Infantry, destined for Fort Shaw, M. T. From Cascade, M. T., he will accompany the portion of the 3d Infantry en route from Fort Shaw, M. T., to Fort Snelling, Minn. S. O. 40, Department of Dakota, May 14, 1888.

ROBERTSON, R. L., first lieutenant and assistant surgeon. Will accompany from Fort Keogh, M. T., the 5th Infantry, to the Department of Texas, returning to his station on the completion of the duty. S. O. 43, Department of Dakota, May 18, 1888.

EWING, C. B., first lieutenant and assistant surgeon. Will accompany the 22d Infantry as medical officer, to the Department of Dakota, returning to his station on the completion of the duty. S. O. 56, Department of Missouri, May 17, 1888.

Paragraph 12, S. O. 49, Department of Texas, May 5, relative to H. S. T. Harris, first lieutenant and assistant surgeon, accompanying 8th Cavalry to Department of Dakota, is amended by Paragraph 1, S. O. 50, Department of Texas, May 9, 1888.

Paragraph 1, S. O. 50, Department of Texas, May 9, is revoked by Paragraph 1, S. O. 51, Department of Texas, May 11, 1888.

HARRIS, H. T., first lieutenant and assistant surgeon. Will be relieved from duty at Camp Peña Colorado, and proceed to San Antonio, where he will report to commanding officer 10th Cavalry, for duty as medical officer with that battalion to its destination in Department of the Platte. Upon completion of this duty, he will return to his proper station, Camp Peña Colorado, Tex. S. O. 51, Department of Texas, May 11, 1888.

WOOD, LEONARD, first lieutenant and assistant surgeon. Leave of absence extended two months. S. O. 114, A. G. O., May 17, 1888.

BANISTER, W. B., first lieutenant and assistant surgeon. Granted leave of absence for two months, with permission to

apply for an extension of twenty-seven days. S. O. 119, A. G. O., May 23, 1888.

Paragraph 15, S. O. 49, Department of Texas, c.s., (relative to Paul Clendenin, first lieutenant and assistant surgeon, accompanying 16th Infantry to its destination), is revoked, by S. O. 51, Department of Texas, May 11, 1888.

CLENDENIN, PAUL, first lieutenant and assistant surgeon. Will proceed from Fort McIntosh to Fort Davis and report to commanding officer 8th Cavalry, for duty as medical officer with that regiment on its march to Fort Concho, from which place Lieutenant Clendenin will return to his proper station. S. O. 51, Department of Texas, May 11, 1888.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING MAY 26, 1888.

DICKSON, S. H., passed assistant surgeon. Detached from the Receiving-ship "Dale" and to Marine Barracks, Washington, D. C.

NASH, F. S., passed assistant surgeon. Ordered to the Receiving-ship "Dale," in addition to present duties.

RUTH, MELANCTHON L., surgeon. Granted one year's leave of absence from date.

SOCIETY NOTICES.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—There will be a meeting of this Society at 19 Boylston Place, on Monday evening, June 4th, at 8 o'clock. Reader: Dr. F. H. Davenport, "Some Gynecological Cases Treated by Electricity."

T. F. SHERMAN, M.D., Secretary.

MAINE MEDICAL ASSOCIATION.—The Thirty-Sixth Annual Meeting will be held in the Common Council Chamber, City Building, Portland, Me., Tuesday, Wednesday and Thursday, June 12, 13 and 14, 1888.

DEATHS.

Died in Groton, Mass, May 24, 1888, Norman Smith, M.D., M. M. S., aged seventy-six years.

Dr. Allan Macy Butler, senior assistant physician at the Roosevelt Hospital, died on Monday. He was a graduate of Harvard, and of the College of Physicians and Surgeons. He was in the twenty-sixth year of his age.

BOOKS AND PAMPHLETS RECEIVED.

Twelfth Annual Report of the Sea Shore Home, for summer of 1887.

The Extraction of Cataract as Influenced by Myological Development. By A. E. Prince, M.D., Jacksonville, Ill.

The Pulley Method of Advancing the Rectus, with Indications for its Employment. By A. E. Prince, Jacksonville, Ill. Reprint. 1887-8.

Clinical Notes on Pruritus. By L. Duncan Buckley, A. M., M.D., Attending Physician to the New York Skin and Cancer Hospital, etc. 1887.

The Census of Massachusetts for 1885. Prepared under the direction of Carroll D. Wright, Chief of the Bureau of Statistics of Labor. Volume III. Agricultural Products and Property. Boston, 1887.

THE PHYSICAL EXAMINATION OF THE STOMACH IN CASES OF GASTRIC DISEASE.¹

BY PHILIP COOMES KNAPP, A.M., M.D.,

Physician to Out-Patients with Diseases of the Nervous System, Boston City Hospital.

HAVING had several patients with digestive disturbances under my care during the summer and fall, I sought in the first place to get a little more knowledge of what had been to me rather an obscure subject. In that way I was led to try some of the recent methods of physical diagnosis in gastric disease. The result of my reading and experience was to convince me of the value of these methods, and, although I have nothing original to offer, I have believed the subject to be of sufficient importance to justify me in presenting what is merely an abstract of the work of others.

Although the Americans are often called "a nation of dyspeptics," the diseases of the alimentary canal have formed, until lately, the most obscure chapter in medicine. We noted a history of vague symptoms—pain, distress after eating, heart-burn, nausea—we looked at the tongue and perhaps at the anus, and imagined what was going on in the twenty-five or thirty feet between. We felt of the abdomen, we regulated the bowels, and we prescribed some one of the many elegant varieties of pepsine which the manufacturers had sent us, and we knew less of the diseases of the alimentary canal than we did of the diseases of the lungs before the days of Laennec. Fortunately we have changed all that—at least in part. In no other branch of medicine, except in bacteriology, have so great advances been made as in the subject of diseases of the stomach. We have obtained the means of determining the action of that organ, and thus we have become able, not only to distinguish more clearly those affections which we formerly knew, but to differentiate other disorders whose existence was before unknown. With this increased knowledge in diagnosis has come even greater skill in treatment. We can compare the action of the diseased stomach with the normal digestive processes, and we can prescribe accurately and definitely, in accordance with the demands of the diseased organ, and not strike out blindly in a dark room with a club. This advance in our knowledge is due, of course, to the methods which have rendered a physical examination of the stomach and its functions possible, and it is to these methods that I would call your attention.

It may be well to preface my remarks with a brief review of the process of gastric digestion. When the food reaches the stomach a part of the starch has already been changed to sugar by the saliva, and may be absorbed by the stomach. It is probable that this action is kept up for a little time in the stomach until sufficient acid has been secreted, for the saliva will still act when small amounts of acid are present (0.01 to 0.25%).² The fats remain unchanged. Salts and water are absorbed directly. Albumen is attacked by the gastric juice, whose active principles are hydro-chloric acid and pepsine. These dissolve the albumen, converting it into peptone, part of which is absorbed by the stomach, while the rest passes on to

the small intestine. The solution and the passage onward are aided by the muscular movements of the stomach. With ordinary meat diet during this process lactic acid is formed³ in from ten to thirty minutes, not secreted by the gastric glands, but formed from the meat itself. This form of lactic acid (Fleischmilchsäure) or sarcolactic acid, disappears at the end of two hours, under the action, probably, of the hydro-chloric acid of the gastric juice which becomes strong enough to prevent fermentation. In disease, where abnormal processes of fermentation are going on, we may get another form of lactic acid (Gährungsmilchsäure) paralaetic acid, isomerically the same, except that it polarizes to the left instead of to the right. In the gastric juice the pepsine seems to act as a pure ferment, aiding the solvent power of the hydro-chloric acid, for Petit⁴ has shown that it will transform one thousand times its weight of fibrine into peptone, and dissolve five hundred thousand times its weight in a few hours. After a certain time, as yet not accurately known, the peptone is more or less absorbed, the rest of the food passes on, and the stomach becomes empty.

Even if the stomach were as accessible to the touch and sight as the mouth is, it is doubtful whether we could get much information as to its diseases by looking at it, for the morbid changes in the functions of a gland are not often due to visible lesions. Of still less value, therefore, is the gastroscope devised by Miculicz. In a few instances it may give some information, but it is not safe to insert such an instrument into a diseased stomach, and the difficulty of manipulation and the cost render it impracticable for ordinary use. By the use of the ordinary soft rubber stomach-tube we can get much more accurate knowledge with much less risk.

From the physical examination of the stomach we obtain information as to the following points: (1) the time of digestion; (2) the absorbent power of the stomach; (3) the motor activity of the stomach; (4) the chemical composition of the gastric juice; (5) the digestive powers of the gastric juice; (6) the size and position of the stomach.

(1) The time of digestion, as I have said, is not accurately known. It varies with the individual and with the character of the food taken. Leube⁵ has found, however, that normally, after a definite meal, all food has disappeared from the stomach at the end of seven hours. In a certain proportion of cases it may disappear before that time, but if, after seven hours, food is found in the stomach, it shows that the process of digestion is delayed. To test this, Leube orders a test breakfast—soup, a piece of beef-steak, and a slice of white bread, with water. At the end of seven hours the stomach is washed out, using about three funnels full of water, and the wash-water is examined for undigested fragments of food. In health the water should contain no such fragments.

(2) The test of the absorbent powers of the stomach is a simple one. Penzoldt⁶ has found that by giving a small amount of iodide of potassium (0.2 grm., gr. iij) in a gelatine capsule with a wineglassful of water at least three hours after a meal, or preferably on an empty stomach, the salt is absorbed, and can be detected in the saliva. The patient is directed

to spit once a minute on a bit of starch paper, which is then touched with a drop of fuming nitric acid. In health, in from seven to fifteen minutes, there is found first a reddening and then a bluing of the paper.

(3) The test of the motor activity of the stomach is equally simple. Ewald⁷ has lately found that salol is changed in an alkaline solution to salicylic acid. The acid gastric juice has no effect on it, but when it passes through the stomach, it is changed to salicylic acid by the alkaline pancreatic juice, absorbed, and eliminated by the urine. The patient is given three to five grains of salol, and specimens of the urine obtained every fifteen minutes or half an hour. The addition of a drop of tincture ferri chloride to the urine will, when it contains salicylic acid, give a deep brownish-red color. This color is said to be found in from half an hour to an hour, after taking salol. If it does not appear until after that time, the motor activity of the stomach is regarded as below normal. Later observers make the time rather longer.

(4) The methods of obtaining the gastric juice, and of testing its chemical composition, have been the subject of much controversy, and the question is by no means settled yet. Leube⁸ suggested three methods of obtaining the juice. The first was by the mechanically irritation of the mucous membrane of the stomach by means of a stiff sound, which naturally proved impracticable. The second was to wash out the stomach with 100 cc. of luke-warm water; then introduce 50 cc. of a three per cent. soda solution, letting it stay twelve minutes, and then adding 500 cc. of luke-warm water, siphoning out, and testing the acidity; alkalinity of the wash-water showing insufficient acid. The third, which was the one he generally employs, is to wash out the stomach, introduce 100 cc. of iced water, letting it stay ten minutes, and washing it out with 300 cc. of water.

Jaworski and Gluzinski⁹ obtain the juice by giving the patient the whites of two eggs, hard-boiled, and 100 cc. of distilled water, at a temperature of 18° C. (65° F.). The patient sits still an hour and a quarter and then the stomach is washed out with 100 to 300 cc. of water. By that time the egg should be digested, and the diluted juice may be tested.

The trouble with these methods is that they give a juice much diluted with water, and therefore estimates as to the acidity or the digestive power of the juice, must make allowance for this dilution. Rigel¹⁰ has therefore sought to obtain the juice in an undiluted form. To this end he passes the stomach-tube during the period of active digestion, two or three hours after a hearty meal, and expresses a part of the contents of the stomach through it. This is filtered, and the filtrates contain the undiluted juice mixed with peptones. The residue, if desired, may be examined microscopically for sarcine, bacteria, etc.

Ewald¹¹ has suggested a modification, giving two rolls, weighing from 30 to 35 grammes, and a cup of green tea without milk or sugar. An hour later he expresses a part of the contents of the stomach in the same way.

As I have said above, at the end of two hours, after a mixed meal, the only acid in the stomach should be

hydro-chloric. If abnormal processes of fermentation are going on there may also be lactic, butyric, or acetic acids. The presence or absence of hydro-chloric acid is therefore the important point. Unfortunately, if any of the organic acids be present, they may respond to some of the tests, and much work has been done to find tests that will show even minute traces of hydro-chloric acid, without re-acting to the organic acids.

First of all, the question of the acidity of the juice should be determined by the use of Congo-red paper, which turns blue when acid is applied. It is rather more delicate than litmus, but the latter should be used as a control.

Then to a little of a concentrated solution of tropæolin (that known to the trade as Merck's 00) spread out on a porcelain dish a drop of juice should be added. If the juice contain hydro-chloric acid it produces first a lilac red and soon a smutty brown color. This change, however, may be produced by a 2 : 1000 solution of lactic acid (Uffelmann).¹²

The test in common use is that with methyl aniline violet. If to a rather dilute aqueous solution of methyl violet a drop or two of gastric juice containing hydro-chloric acid be added, the color changes to blue.

Ewald and Boas¹³ and Uffelmann, make more or less use of Mohr's test. This consists in adding a couple of drops of juice to a layer of the following mixture:

Liquor ferri acetici (C. P.)	0.5
10% sol. potass. sulpho-cyanide	2.0
Aqua dist.	10.0
M	

This forms a clear ruby-red solution. If hydro-chloric acid be added it turns violet, and later a mahogany brown.

Rhode's¹⁴ test consists of equal parts of a half per cent solution of ammoniac sulpho-cyanide and a fresh solution of tartrate of sodium and iron oxide, which becomes brown-red with dilute solutions (0.25 per cent.) of hydro-chloric acid.

Von den Velden¹⁵ recommends a solution of fuchsin (rosaniline chloride) which loses its red color with hydro-chloric acid.

Uffelmann¹⁶ is a strong advocate of two tests. The first is by use of the coloring matter of red Bordeaux wine. The wine must respond to various tests, for which I will refer to his original paper. One cc. of this wine is shaken with three cc. of absolute alcohol and filtered. He then wets paper with this filtrate, dries it in a cool place, and uses it like litmus. Hydro-chloric acid changes it from a bluish-red to a rosy red. His other test is a paper soaked in the juice of huckleberries which is turned red by hydro-chloric acid.

Von Jaksch¹⁷ quotes Voigt as recommending a solution of emerald green (the "krystallisirte" of B. Bayer), which is changed to a grass or yellow green by dilute hydro-chloric acid, while organic acids have no effect, and mentions several similar colors which are less sensitive.

Cahn and v. Mering¹⁸ have devised a very elaborate method of determining the presence of hydro-chloric acid, even in minute quantities, by distillation

and digestion with cinchonine, but it is too complicated for ordinary clinical use, so I will not describe it here, although I shall refer to the conclusions which they draw from it later.

Finally, I will mention a new test described by Günzburg,¹⁹ which I learn from Dr. J. W. Warren is very trustworthy and satisfactory. He uses the following solution:

Phloroglucin (Merck's)	2.0
Vanillin	1.0
Alcohol (absolute)	30.0

This gives a yellow-red solution. If a few drops of this be added to an equal amount of gastric juice containing hydro-chloric acid and gently warmed on a porcelain plate, deep-red crystals are formed. This solution reacts to very small amounts of hydro-chloric acid, 0.01 per cent. and less, and does not react, even to concentrated organic acids. Dr. Warren regards it as the only satisfactory test.

The presence of pepsine is to be determined by a digestive experiment. The detection of peptones is not very important. The test is simple, however, and is the ordinary biuret reaction. The solution is diluted, rendered alkaline by sodic hydrate, and a few drops of a dilute solution of cupric sulphate are added. If peptones be present, the solution turns a rosy red, but if albumen be present alone, it turns violet. (Sticker).²⁰

The test for the acids found where there is fermentation is much simpler, or rather all authorities agree. Uffelmann²¹ has proposed a test for lactic acid which is generally accepted. He takes one or two cc. of the following solution:

4% sol. acid carbolie	10.0 cc.
Aqua distill.	20.0 cc.
Liq. ferri sesquichlorid. (F.G.)	one dr. p.

This forms a steel-blue solution, which is decolorized by hydro-chloric acid, and turned yellow by lactic acid.

If the juice be shaken with ether, and the ethereal residue evaporated, acetic and butyric acids can be detected by the smell. On neutralizing the ethereal solution with sodic carbonate and adding the iron solution, acetic acid will turn it blood-red. On adding distilled water, a drop or two, and a bit of calcic chloride, oil drops of butyric acid will appear on the surface. These tests, however, are unimportant.

Having determined the presence or absence of hydro-chloric acid, the juice should next be subjected to a quantitative determination of the acids. Uffelmann gives the following approximate tests:

Huckleberry juice shows	0.024% hydro-chloric acid.
Tropeolin shows	0.03% "
Methyl-violet shows	0.038% "
Wine test shows	0.045% "

Von den Velden²² thinks the normal amount of hydro-chloric acid is 0.12%. Ewald²³ thinks the normal limit varies between 0.15% and 0.4%, with the normal average of 0.2%, and other observers think that a percentage above 0.25 or 0.3 is to be regarded as suspicious. For an accurate test, only a small amount ($\frac{1}{2}$ to 1 cc.) of the juice is necessary. This is diluted with a weak solution of phenol-phthalein, and the decinormal sodic hydrate solution is run into it from a burette until a red color persists. The amount of acid is then easily calculated, as the decinormal

sodic hydrate solution contains 4 mgr. to the cubic centimeter.

(5) As I said before, the presence of a sufficient amount of pepsine is best shown by testing the digestive power of the stomach. The test is very simple: A bit of egg-albumen is put into a test-tube containing 10 to 20 cc. of the juice, and kept at the temperature of the body. For this purpose, it is well always to take a piece of the same size. Sticker²⁴ advises a disc 8 mm. across and $1\frac{1}{2}$ mm. thick. I have used a bit measuring 8 x 4 x 1 mm. If the juice be undiluted, this should be digested in from two to three hours. With diluted juice, the time, of course, will vary. If juice enough be obtained, it is well to perform control experiments at the same time by taking three test-tubes and leaving one untouched, adding a drop of dilute hydro-chloric acid to the second, and a flake of pepsine to the third.

(6) The determination of the size and position of the stomach is of importance chiefly in cases of suspected dilatation, and various methods have been devised for this purpose. Palpation and percussion may furnish some slight aid, but, as a rule, other methods are necessary. Leube²⁵ passed a stiff sound into the stomach, and endeavored to feel the point through the abdominal wall, but this procedure is not easy in stout patients, and is full of danger. Penzoldt²⁶ had the patient take considerable water, and thus mapped out the lower border of the stomach by detecting the dulness. Schreiber²⁷ tied a rubber balloon to the end of the stomach-tube, and thus inflated the stomach. Neubauer²⁸ and Fleischer²⁹ determined the level of the liquid in the stomach by connecting the stomach-tube with a U-tube outside the body. Rosenbach³⁰ put water in the stomach, passed a tube into the water, and then, auscultating over the abdomen while he pumped air into the stomach, determined, by listening to the bubbles rising through the water, the upper level of the fluid. Kussmaul³¹ inflates the stomach by generating gas within. For this purpose, he gives 2 grm. of bicarbonate of soda and $1\frac{1}{2}$ grm. of tartaric acid, and the size of the stomach when filled with the gas thus generated can readily be determined by palpation and percussion. In using this method, a stomach-tube should be in readiness in case unpleasant symptoms should arise from over-distension. Purgess³² taking the average distance from the incisors to the cardiac orifice, finds how much farther the sound can be pushed downwards—a method applicable only with the stiff sound, and liable to the same objections as Leube's method.

Having spoken at length of the various methods recommended, before speaking of the conclusions to be drawn for diagnosis from these tests, I will briefly describe the methods of procedure which I have selected as best adapted for use for clinical purposes—substantially those of Riegel.

The patient's history should first be taken, and, if there is a recent history of hæmatemesis, the tube should not be used. The abdomen should be carefully examined, inspected, palpated, percussed, and auscultated. The chest should also be examined, for

²³ Ewald. Op. cit.

the tube should not be used if there is a thoracic aneurism. Leube recommends a tube of 11 mm. diameter (33 French), with a calibre of 7 mm., but a smaller one will answer — my own is about 9 mm. (25 French). The patient should sit erect, the head thrown a little back, the mouth well open, and the tongue may be depressed and pulled forward a little by a spatula or the left index finger. The tube is then passed into the fauces, past the epiglottis, and into the pharynx. Once engaged in the œsophagus, there is no further trouble, except that it may stick for a moment at the cardiac orifice. If it does, a little water poured into the tube will overcome this obstacle. If the patient begins to retch or to show signs of suffocation, he should be told to take deep breaths. It is rarely necessary to withdraw the tube. It is certainly not easy to get a tube into the larynx of a sane man. If cocaine be used — and it makes the process easier — such an accident may be possible, although I doubt it. It is well to wait a moment, however, to see if the patient breathes naturally. When the tube reaches the stomach, it generally happens, unless the stomach be quite empty, that we hear a bubble or two of air come up the tube — a point mentioned at a meeting of the Section a year or two ago by Dr. Boland. I have found that milk is a good material to lubricate the tube with to facilitate the introduction, being much less nauseating than vaseline or oil. To wash out the stomach, a piece of rubber tubing is connected with the stomach-tube, with a funnel at the end, and about a pint of warm water is slowly poured into the funnel, holding the funnel end well up. By suddenly lowering the funnel, the contents of the stomach may thus be siphoned out. In withdrawing the tube, care must be taken to compress the end tightly before withdrawal, so that the contents of the tube may not drop into the larynx. If the tube be passed through the nostril — the favorite way of introduction when it is used for feeding the insane — the patient may lie down. In the cases that I have tried, it seems less disagreeable to the patient to pass it through the nose, but as I never tried both methods on the same patient, it is hard to make comparisons. Patients sometimes get so used to the passage of the tube that they will swallow it down themselves. The dangers of the procedure are slight, less than those of catheterizing the bladder. The chief risk, of course, is of passing the tube into the trachea and setting up an inhalation pneumonia, but this is not great, except among the insane. Slight traces of blood are of no account. One patient reported to me raising half a teacupful of "blood and corruption" after the first passage of the tube, but it seemed to do no harm. It might be well to tie a string to the tube, for in a case reported the whole tube was swallowed.

Having taken the patient's history, and made a careful external examination, I prefer first to get a specimen of the gastric juice. This I do by expression by Riegel's method, having the patient come to me about three hours after a meal. Having passed the tube, external pressure over the abdomen, or a voluntary effort on the part of the patient, will generally press out a certain portion of the contents of the stomach. Having filtered it, I test the acidity of the filtrate by litmus and Congo papers, and then I have thus far tested for free hydrochloric acid with tropæolin and methyl violet. Hereafter I shall use Günzburg's test. I then test for lactic acid with Uffelmann's reagent, reserve about 1 cc. of the juice for a quantitative test, and, if there is enough, divide the rest of the juice into three parts to test its digestive power. All this requires only about an ounce of gastric juice. If abnormal fermentation is suspected, I shake with ether, and smell the residue to detect butyric or acetic acid. The next day, or later, I prescribe Leube's test breakfast — soup, steak and bread — taking care to measure the size of the steak and bread taken, and the quantity of soup. Seven hours later I wash out the stomach, taking care that the patient eats nothing between whiles. During one of the visits Penzoldt's test for absorption may be made, and between them the patient may be given a dose of salol with instructions to save several specimens of urine passed every half-hour after taking it. For determining the size of the stomach Penzoldt's fluid test is the simplest, but, if it prove unsatisfactory, it may be supplemented by Kussmaul's test.

What do we learn from all this? What is the good of such an examination, which seems so elaborate, yet which is really comparatively simple — less difficult, except as far as obtaining the juice, than a thorough examination of the urine? By it, as I said at the beginning, our knowledge of diseases of the stomach has been put on a firm foundation. I am so fully convinced of the value of these methods that I am ready to say that a man who tries to treat a serious and obscure case of gastric disturbance without resorting to them, is as guilty of negligence as the man who tries to treat an obscure case of thoracic disease without using the stethoscope.

The most important question refers to the presence or absence of free hydro-chloric acid in the gastric juice. The weight of evidence is decidedly in favor of the opinion that in cancer of the stomach there is no free hydro-chloric acid in the gastric juice. The chief authority opposing this view is that of Cahn and von Mering, who, by the method spoken of above, have found acid in cancer. Rosenbach⁵⁵ alone claims to have found hydro-chloric acid in cancer by the ordinary tests. The experiments of Cahn and von Mering, however, have recently been repeated by Honigmann and v. Noorden,⁵⁶ who believe that the juice in cancer does not contain the free acid, but acid combined with unstable albumen derivatives, which are broken up by the method employed. If, then, the gastric juice constantly reacts to the ordinary tests with tropæoline and methyl violet, it is safe to say that there is not cancer. The absence of hydro-chloric acid, however, is not pathognomonic of cancer, for it has also been found absent in atrophy of the stomach, and in the backward flow of bile (Riegel),⁵⁷ in any local disease of the stomach, and temporarily in catarrh, from increase of mucus, and in febrile diseases (Edinger).⁵⁸ In such cases the time of digestion is, of course, prolonged, and the digestive power of the juice is impaired, even if hydro-chloric acid is added, showing that there is a decreased amount of pepsine.

In contradistinction to the cases where hydro-chloric acid is absent come those where it is increased, or where there is a continuous secretion of gastric juice (Reichmann,⁵⁹ Riegel).⁶⁰ This condition gives rise

to thirst, heart-burn, pain at night, and acid vomiting. The stomach must be washed out at night, and then the tube passed before breakfast the next morning. In these cases the stomach is found to contain 180 to 300 cc. of an acid fluid, which digests albumen, and gives the reactions for hydro-chloric acid. This is the only pathognomonic test for this condition. The amount of acid may also be increased to 0.3% and over.³⁹ Riegel⁴⁰ believes this condition to be quite common. It is of especial interest as pointing to a possible cause of ulcer, the extreme acidity of the juice rendering self-digestion easier. Some of the symptoms are like those of ulcer, and in ulcer there is usually an extreme acidity of the juice.⁴¹

The detection of other acids points to abnormal processes of fermentation going on in the stomach, as in catarrh or dilatation of the stomach. The significance of the digestive test has been mentioned in connection with the absence of hydro-chloric acid. The tests for absorption and muscular activity have been too little studied as yet. The muscular activity would naturally be diminished in dilatation, where the methods for determining the size of the stomach are also called for. When there is digestive disturbance, but the stomach digests a test breakfast in seven hours, and the juice is normal, the condition is often spoken of as "nervous dyspepsia."⁴² Many cases are undoubtedly due to some nervous disorder, while in others the absorbent power and the muscular activity of the stomach have not been carefully tested. Where there are other signs of a neurotic condition the term may be used, but at best it is vague, and in many cases we can define the numerous nervous affections of the stomach more exactly.

What do these new methods teach us in regard to treatment? Enough to cause us to alter our present methods. In the majority of cases there is a normal or excessive amount of hydro-chloric acid, hence the common exhibition of it is needless, and often injurious. Where the acid is in excess we should not depend on alkalis. The stomach should be washed out at night, Carlsbad water given in the morning, and the stomach given increased work by giving the patient an albuminous diet, avoiding carbohydrates.

When acid is absent, or much diminished, the ordinary dose ($\pi v-x$) is much too small. Ewald⁴³ has calculated that to render neutral juice properly acid, thirty to forty-five minims should be given after each meal, in three doses fifteen minutes apart, beginning about an hour after meals. When acidity of the stomach is due to lactic acid, from fermentation, this should not be combated solely by alkalis, although Carlsbad may be used. The stomach should be washed out, and hydro-chloric acid given, for it will be remembered that when hydro-chloric acid is formed during digestion it checks the formation of lactic acid. In catarrh and dilatation washing out the stomach is a remedy to be first employed. In muscular insufficiency strychnine and very mild faradic currents may prove serviceable. In "nervous dyspepsia," as I have long believed, special treatment is uncalled for; we must build up the nervous system, and the stomach will take care of itself.

I have said nothing of that panacea for all disturbances of digestion, of which at least nineteen varieties are brought to our attention weekly, namely, pepsine. I have always acted on the statements which the physiologists have been making for years, that pepsine is required for digestion only in small amounts, and that hydro-chloric acid was the important factor. In the great majority of cases there is plenty of pepsine in the gastric juice, and the addition of any more is needless, and therefore wrong. In a few instances where partly digested food is to be given, pepsine becomes necessary in its preparation, otherwise the use of pepsine is thoroughly unscientific.

I have dwelt chiefly upon the methods of research, referring briefly and cursorily to these points where they throw light on the diagnosis and treatment. The thorough examination is not agreeable to the patient, although it is not dangerous, and it takes a certain amount of time and trouble. I can merely repeat that the more I try it the more firmly I am convinced of its value and necessity, and I fully agree with Ewald's dictum.⁴⁴ "I grow more convinced daily that an exact diagnosis of gastric diseases, and a sound treatment based on it can be obtained only by a careful chemical examination of the gastric juice or the gastric contents by the methods of qualitative and quantitative determination of acids as given above."

AN EXERCISE IN THE EXTEMPORIZATION OF LITTERS FROM RIFLES AND GUNSLINGS.

BY JAMES E. PILCHER, M.D., PH.D.,
Assistant Surgeon in the United States Army.

For a number of years past, the subject of the conveyance of the disabled as an important part of early aid in accidents and emergencies, has been a popular one. The St. John's Ambulance Association in England, the Samaritan Societies in Germany, and still other bodies in other countries, all serving under the Red Cross, have contributed to this end. Foreign armies have long possessed thoroughly organized corps devoted to this work, and now the National Guard of many of our States is provided with an ambulance corps, while the regular army, with its hospital corps supplemented by four "company bearers" from each company, troop, and battery, has a foundation upon which is being erected a system of "first aid" that will be a material advance upon the work already done. In a recent lecture before the Military Service Institution, the writer presented some of the results of a considerable number of experiments as to the best methods of conveying the disabled by human bearers. The well-known method of carrying the disabled upon a litter extemporized from two rifles and their gunslings was particularly pleasing to many, and a strong desire has since been expressed for a system of movements by which such a litter could be constructed with the least confusion and delay.

In deference to this desire, the following exercise has been devised. Unless otherwise specified, the movements are to be executed in accordance with the authorized United States Infantry tactics:

The bearer company or squad being formed in two ranks, with their pieces at "carry arms," the medical officer commands, (1) *Rear open order*, (2) *MARCH*, which is performed in the usual manner. He then

³⁹ Von den Velden. Volkman's klin. Vorträge, No. 290, 1886.

⁴⁰ Riegel. Zeitschr. f. klin. Med., xii, 426, 1887.

⁴² Leube and Ewald. Verhandl. d. Congress. d. inner. med., iii, 204, 1884.

⁴³ Ewald. Berlin. klin., Wochenschr., No. 3, 4, 1886.

⁴⁴ Ewald. Klinik der Verdauungskrankheiten, I, 107, 1886.

continues, (1) *Front rank, about*, (2) *FACE*. After this command is executed, he commands, (1) *Order*, (2) *ARMS*. The company is now prepared to construct the litters. Accordingly, the medical officer commands, (1) *Prepare*, (2) *LITTER*.

At *litter*, each man grasps the barrel of his rifle just below the muzzle, and lifts it directly forward until the stock rests upon a point midway between the front and rear rank. Each rear rank man lets his gunslung out to its greatest length; at the same time, the front rank man frees the upper end of his gunslung entirely from his piece. The rear rank man passes his gunslung over the rifle of the front rank man, and then, with his left hand, grasps the rifle of the front rank man, just below the muzzle; the front rank man then passes his gunslung about the rifle of the rear rank man, and, drawing it through the upper ring of his own rifle, hooks it at its greatest possible length, and then faces about to the front.

The medical officer then commands, (1) *Carry*, (2) *LITTER*.

At *litter*, the front rank man stoops and grasps the stocks of the rifles, and he arises to an erect posture holding them in his hands, with his arms extended by his side; at the same time that the front rank man arises with the stocks, the rear rank man lowers the muzzles until they are held by his side also.

It is now seen that an excellent litter has been formed with the rifles as the side poles, and the interlacing gunslings as the bed. A disabled man should be carried on this litter in a sitting posture, leaning back upon the chest of the rear bearer. To place a patient upon this litter, it should be lowered to the ground in obedience to the command, (1) *Lower*, (2) *LITTER*, and the patient made to sit upon it, facing in the direction of the stocks. It should then be lifted in obedience to the command, (1) *Lift*, (2) *LITTER*.

If it is desired to separate the litter again into its component parts, the medical officer commands, (1) *Order*, (2) *LITTER*.

At *litter*, the front rank man lowers the stocks of the rifles to the ground, and faces to the rear; the rear rank man, retaining his grasp at the same point upon the rifle-barrels, draws the stocks to a point midway between the two ranks, raising the muzzles to the height necessary to hold them easily in front of him.

The medical officer then commands, (1) *Break*, (2) *LITTER*.

At *litter*, the front rank man unhooks his gunslung and removes it from the rifle of the rear rank man, seizes his rifle and withdraws it from the gunslung of the rear rank man. Both bearers fasten their gunslings in the original position and bring their pieces to "order arms." The medical officer then commands, (1) *Carry*, (2) *ARMS*, following with (1) *Front rank, about*, (2) *FACE*, and bringing the company back to its original formation by the command, (1) *Close order*, (2) *MARCH*. The company is then dismissed in the usual way by the commands, (1) *Arms*, (2) *PORT*, and (1) *Break ranks*, (2) *MARCH*.

A litter extemporized in this manner has been shown by experience to be of the greatest value in the field, where the accessories of litter-bearing are very apt to be deficient or entirely absent. Its construction is equally adapted for any number of men from two to a hundred. A bearer company carrying this variety of extemporized litter may be manoeuvred in exactly the same manner as an infantry company in

double rank formation. The evolutions are exceedingly effective, and, while not the less useful in actual service, are particularly adapted to exhibition occasions.

REPORT OF PROGRESS IN ORTHOPÆDIC SURGERY.¹

BY E. H. BRADFORD, M.D., AND R. W. LOVETT, M.D.

THE MECHANICAL PRODUCTION OF KNOCK-KNEE, FLAT-FOOT, ETC.

It is impossible, in the short space available here to do justice to Mr. Arbuthnot Lane's very admirable paper² on the pathology and physiology of the deformities of young life. One line of argument runs through it all, that the cause of all these deformities (knock-knee, flat-foot, lateral curvature, etc.), is mechanical, and brought about by the child's habitually assuming what he calls "attitudes of rest." Take knock-knee for example, in the erect position when the heels are together the femur and tibia form an angle open outward, and the external condyle transmits the body weight more than the inner one. A persistent assuming of this position, or even a more extreme one, with the feet apart, by even a healthy child, would be apt to lead to atrophy of the cartilage of the external condyle where the pressure comes, and hypertrophy of the inner one (in a former paper Mr. Lane has demonstrated these pressure results in healthy adults), and knock-knee results. If the assumption is correct, the wonder is, as the writer says, that so few children have knock-knee. The treatment of early cases should be to raise the inner side of the sole. Flat-foot often coexists with knock-knee, not that one is the result of the other, but that both are the results of this assumption of attitudes of rest. Partial adduction of the foot is the position of activity. Abduction, the position of rest assumed in the easy erect posture. Abduction habitually assumed, leads to rotation of the os calcis, and displacement of the astragalus and yielding of the ligaments come secondarily. Treatment should be directed to repairing the loss of tone and vigor, low-heeled boots should be worn, exercises should be adopted to strengthen the adductor muscles of the foot, and if necessary, some of the numerous mechanical devices should be resorted to. Round shoulders and lateral curvature in the same way are traced to static causes. One statement with regard to the latter might be questioned; "You can get no lateral flexion of the dorsal spine unassociated with what is called a rotation of the bodies of the vertebrae around a vertical axis."

With regard to rachitic deformities of the legs the ordinary cause is asserted to be a rotation of the sacrum, apparently in consequence of the flexed spine. The pelvis rotates secondarily, the ilio femoral ligaments are consequently strained upon and the child stands with thighs necessarily flexed. In this position the weight of the body falls inside of the knees and a tendency to bow-legs results. The treatment should be extension of the thighs and pelvis in the recumbent position.

LOOSE BODIES IN THE JOINTS.

König³ writes opposing the theory that loose car-

¹ Continued from page 522.

² Guy's Hospital Reports. 1887. p. 241.

³ Deutsch. z. f. Clin., Bd. xxvii, Heft. 1 and 2, p. 90.

tilages are so frequently produced by actual tearing off of the articular cartilages by a wrench or a strain, as Hueter, for example, supposes. Rather, he says, consider them the result of a local necrosis, produced by the injury and consequent inflammation which has lead to their separation. He does not attempt to deny that an actual tearing off does occur, but he thinks it very uncommon and only to be produced by very great violence. The process which sets free the necrotic pieces, he classifies as an osteochondritis of spontaneous origin. He alludes to the frequent occurrence of these free bodies in the elbow, as well as in the knee.

Professor Humphrey²⁵ went so far as to deny the possibility of the formation of these loose bodies by the detachment of pieces of the articular cartilages, and he adds: "I can scarcely suppose that any one really believes that a portion of bone detached by the process of necrosis, can be converted into one of these bodies."

Mr. Howard Marsh²⁶ replies to him and mentions a specimen in St. Thomas' Hospital Museum where Mr. Simon removed a loose body from the knee-joint, consisting of a piece of cartilage with adherent bone, evidently freshly chipped off of the end of the femur.²⁷ With regard to a piece of bone becoming converted to one of these bodies, a case of Mr. Teale's showed a loose body which fitted exactly into a breach made in the inner condyle of the femur, and Mr. Marsh quotes four other cases in support of the view that these bodies are certainly sometimes clearly caused by tearing off small pieces of cartilage and bone.

WRY-NECK.

Mr. Keetley²⁸ would confine the term "wry-neck" to contraction of the sterno-mastoid muscle and to that alone, and he advocates the operative treatment as soon as ever the wry-neck has actually developed. Mechanical treatment, without operation, except in very rare cases, he condemns. The methods are of course two, subcutaneous and open division of the muscle. He first does the subcutaneous operation, and if rectification is not possible after that, he at once passes on to the open method and cuts the bands still resisting. Extension and counter-extension are then made "by weights attached by adhesive strapping to the head and upper arm respectively," commencing with two weights of four pounds each, and extension should be kept up a month and followed by daily manipulations to keep the head in place.

Dr. J. J. S. Davis²⁹ in writing of congenital torticollis, gives a very complete bibliography of the subject and sums up a somewhat long article as follows:

(1) "That it is rare and doubtful if ever congenital torticollis is produced through the act of delivery . . . but that the cause may often be found in the low vitality of the fetus of scrofulous parentage; (2) that complete resection of all the contracted tissues is necessary before attempting to restore the head to its normal position; and (3) that it should be kept in the normal position ten or fifteen days.

DISEASE OF THE ELBOW-JOINT.

Kummier³⁰ in a most thorough article on disease of

the elbow-joint has found, in a large number of cases, no instance of general milary tuberculosis caused by operative interference, as claimed by König; and operative treatment is especially advocated in severe forms of the disease, either complete or partial resection, arthrectomy, or evidement. In complete excision, Ollier's Z-incision is to be preferred, and no attempt should be made for first intention in fungous disease, to the sacrifice of thorough drainage. Excision for the cure of ankylosis has not, in the hands of the writer, given satisfactory results, as a rule. The conservative treatment, fixation, etc., through of use in the lighter cases, is not satisfactory in the severe tuberculous cases.

Mr. Thomas³¹ under the heading of "Contributions to Surgery and Medicine," gives first, some valuable hints about the diagnosis of early Pott's disease, and mentions brown paper wet and bound on as a sufficient treatment for early cervical disease in infants. When deformity has occurred in the spine anywhere he advises against all treatment which is calculated to lessen the angular deformity, and he says that he uses himself the "dorsal cuirass," advocated by Dr. Baner.³² Of plaster-of-Paris jackets Mr. Thomas speaks as follows: "I am equally convinced that the plaster-of-Paris casing, now so popular, is the most inefficient and irrational of all forms in use." With regard to disease of the elbow-joint he insists that the joint should be put up at the angle of 45° as giving better rest to the muscles, and if ankylosis does take place, as affording a more useful arm. The remainder of the book is devoted to questions of general surgery.

ORTHOPEDIC TREATMENT OF PARALYSIS OF THE ANTERIOR MUSCLES OF THE THIGH.³³

The disability of patients affected with paralysis of the extensor muscles of the thigh is well-known to be very great, and Jndson calls attention to the occasional amputation of such limbs on this account. The treatment which he proposes is very simple; by means of a steel upright running up the inside or outside of the leg terminating below in a club-foot retentive shoe, with a joint at the ankle; an anterior steel arm embraces the limb above the knee, and high up on the thigh a posterior arm half encircles the leg. In this way the knee is kept from bending, and the whole leg is supported.

OPERATIVE TREATMENT OF PARALYTIC JOINTS.

Zinsmeister³⁴ writes of the procedure of making an artificial ankylosis in joints which are useless from paralysis. Albert was the first to suggest and perform an operation in a case of infantile paralysis resecting the knee. Winiwarer has repeated the operation, Wolff has done the same thing for the shoulder, and Lesser and Rydiger on paralytic varus. The result in all these cases were excellent. Albert has recently operated on 10 patients; 14 operations, 5 in the knee, and 9 in the foot. In 8 of the cases the paralysis was due to acute poliomyelitis, and in 2 this followed apparently an acute infectious disease. The results were satisfactory in all. Six weeks after the operation, as a rule, the patients were able to go about. The operation is especially indicated for the poor who are

³⁴ Deutsche Zeitschrift für Chirurgie. Bd. xxvi, p. 498.

unable to procure appliances for locomotion. Albert does not advise a typical resection, but a simpler procedure; namely, the removal of the cartilaginous surface of the joint. This is sufficient for ankylosis, and wiring of the bones is not necessary. It is not necessary to remove the synovial membrane. It is reported by the writer that a typical aseptic first intention without suppuration does not give as firm an ankylosis as if there is some suppuration, and he advises keeping a small layer of iodoform gauze in the wound until slight suppuration takes place. In paralytic club-foot it is better to remove the astragalus.

Roser⁶⁵ reports a case of absorption of the head of the humerus, the formation of a loose joint somewhat similar to that seen following tabes dorsalis, where no disease of the chord existed.

The affection was chronic and painless. It developed in an adult secondarily to a plegmon of the hand, but no pain, stiffness, or loss of function of the affected shoulder existed. On examination an abnormally loose shoulder-joint was found, with friction on moving the shoulder forcibly. A cold abscess had formed around the shoulder. Excision of the shoulder was performed, and the head of the humerus and the opposing surface of the acromion was found absorbed, as was also the long head of the biceps and the tendons of the supra and infra spinatus.

SECONDARY SYPHILITIC AFFECTION OF THE JOINTS.

Cayla⁶⁶ reports two cases with a syphilitic affection of the synovial membrane of the knee-joint, occurring during the secondary stage of syphilis, which disappeared under anti-syphilitic treatment and immobilization. The pain was not severe, and the effusion was not great. There was no redness or symptom suggesting articular rheumatism. Cases of the sort are quite uncommon, but have been observed in Fournier's clinic.

THE RELATION OF SYPHILIS TO RICKETS.

MM. Cuzin and Iscorresco,⁶⁷ after an extended study of this subject, arrive, among others, at the following conclusions: The bony lesions in the two conditions are either quite different, or are common to other diseases. Syphilitic bones never present the spongy tissue peculiar to rickets. Rachitic bones never show the characteristic multiple osteophytes of syphilis. Anatomically the two processes are entirely distinct. Syphilis may precede, but cannot be viewed as giving rise to rickets, though it sometimes produces osseous deformities, which may be included within the general title of pseudo-rachitis.

Moncorvo,⁶⁸ writing of his experience in Rio Janeiro, allows that hereditary syphilis furnishes 60% of the cases of infantile disease. These and rickets he finds present in 45% of the children coming under his observation. More than two-thirds of the rachitic children in his practice show signs of syphilis, and it is rare to find a child with hereditary syphilis whose bones are not rachitic.

SPINA BIFIDA.

Rocklinghausen⁶⁹ has investigated thirty-one cases of congenital deformity of this sort with a view to es-

tablishing the pathology of the affection, and they confirmed the Daresti-Koch theory that the cord in such cases remained in the stage of the medullary plate, and not that the medullary canal was primarily closed and then opened by what was called hydromyelia. It was found that the exterior of the cyst wall was not dura but pia mater. Pressure is asserted to be the fundamental cause in all the varieties, and not, as in the old view, an embryonal hydromyelos.

Sutton⁴⁰ reports a case of spina bifida occulta, where there were also present lateral curvature, talipes equinus of the left foot, atresia ani, imperforate pharynx and single kidney.

CLUB-FOOT.

Shaffer,⁴¹ speaking of Phelps's method of treating club-foot by open incision, says that many cases apparently to be classed as "inveterate" yield readily to simple mechanical treatment, while on the other hand, apparently simple cases offer much difficulty. His own experience leads him to divide congenital club-foot into three varieties: (1) muscular; (2) ligamentous; (3) osseous; but a clinical distinction is not always to be made between them. The method of treatment which he advocates is, to start with an efficient traction apparatus, and if, after a sufficient length of time, the deformity does not yield to this, to proceed to tenotomy and subcutaneous division of the ligaments, and then to go on with traction as before. Under these circumstances open incision and osteotomy will be rarely called for.

CONGENITAL TALIPES EQUINO VARUS.

A very valuable article is contributed by Mr. C. L. Scudder,⁴² of the Harvard Medical School, embodying the results of many original dissections of cases of talipes, as well as of the fetal foot, and his conclusions are:

(1) The obliquity of the neck of the astragalus is greatest in cases of varus, less in normal, and least in adult feet.

(2) A change in the obliquity of the neck of the astragalus is a part of the development of that bone, whether it be in a normal or varus foot.

(3) In all probability this obliquity of the neck of the astragalus offers greater resistance to the reduction of the deformity in cases of congenital varus or equino varus past the first few years of life than has hitherto been supposed.

With regard to Berg's theory of retarded inward rotation of the thigh as the cause of the deformity, Mr. Scudder concludes from an examination of sixty-nine fetuses, "that the position of varus or varo-equinus with rotation outward of the thigh is present in all twelve fetuses of the average age of six weeks." That for the same age beyond six weeks neither the position of the feet nor the degree of the rotation of the thigh inward is constant. That rotation of the thighs outward is quite a constant phenomenon, occurring in fifty-one out of the sixty-nine cases; and the cases which showed no rotation were, as a rule, older than the cases presenting outward rotation. That there is probably no necessary connection after the sixth week of fetal life, between the age of the fetus, the rotation of the thighs, and the position of the feet. As to the

feet alone, "as the age increases the varosity, if I may be allowed the expression, decreases." And from an examination of hospital cases in very young children, he concludes that Berg's statement "that the leg is rotated outward in all cases born with this deformity" is incorrect.

CLUB-FOOT.

At the beginning of his article, Dr. Hawes⁴⁶ remarks that "to the average practitioner, distant five hundred miles from the nearest instrument maker, the treatment of talipes by the aid of an ill-fitting club-foot shoe is annoying and unsatisfactory," and he advocates the use of a simple home-made apparatus, which he has found of much use. Two pieces of thin board are hinged together, one piece to go back of the legs and one under the feet. Each leg is secured by straps to the larger piece of board passed about the calves and ankles. On the smaller piece of board are screwed two strips of metal, which are applied to the inner side of the foot from the instep to the base of the toe, in such a place that the foot is held in the normal position. The equinus can be corrected by tightening a cord which connects the free edges of the two pieces of board. From the cut it would appear that the apparatus would produce eversion rather than correction of the deformity. However, in using it Dr. Hawes finds "that in the majority of cases, by its use, aided by local stimulation, the child is ready to dispense with all appliances when old enough to walk."

ANEURISM AFTER TENOTOMY FOR CLUB-FOOT.

Walsham⁴⁷ reports the appearance of an aneurism as large as a marble two weeks after a subcutaneous division of the plantar fascia in a boy seven years old. There was a smart hemorrhage from the wound at the time of operation, but it was easily controlled, and the usual plaster-of-Paris bandage was applied. Mr. Walsham thinks that a wound of the artery is not uncommon, but the subsequent development of an aneurism is certainly very rare, and in this case, perhaps, to be attributed to the fact that the mother allowed the child to walk too soon. In this case the aneurism was cured by pressure over the posterior tibial artery, which was maintained for two months.

DISTORTION OF PELVIS CONSEQUENT ON CLUB-FOOT.

Meyer⁴⁸ reports that the rotation of the limb consequent on club-foot necessarily alters the flexion-plane of the knee, bending the knee forward with some rotation; also throwing the pelvis forward, necessarily causing an alteration of the shape of the acetabulum and of the head of the femur. A slight narrowing of the pelvis (cross diameter) also occurs, as well as an increased lordosis of the spine.

TREATMENT OF CLUB-FOOT.

Krauss⁴⁹ advises the use of simple appliances in the treatment of club-foot, making the surgeon independent of the instrument-maker. He makes use of a simple appliance, consisting of a wooden sole-plate with a steel upright on the outer side of the leg, and an arrangement for increasing pressure (by means of a screw) for the inner sides of the metatarsal and great toe. The appliance is covered with thick felt, and the foot and ankle secured to the wooden sole-

plate by means of plaster-of-Paris bandages applied over the stocking, and without much cotton applied to the foot. Correcting-screw pressure is exerted upon the foot secured by the plaster bandages.

Tenotomy of the tendo-Achillis is not needed in young children, but in older cases the tendons and fascia should be divided. This has to be repeated in the severest cases. The results reported are most excellent, and are quite numerous.

Clinical Memoranda.

TYPHOID FEVER IN A CHILD THREE YEARS OF AGE.

BY EDWIN FARNHAM, M.D., CAMBRIDGE, MASS.

As records of the temperature curve of typhoid fever occurring in young children are, according to my experience, comparatively rare, the following case may be of interest.

October 3, 1887, this child's father who had been feeling poorly for some days went to bed and developed an attack of typhoid fever of medium severity. November 1st he was convalescent, and about this time the daughter complained of being tired after going out, was fretful, and indifferent to what usually interested her, and in the afternoon was hot and flushed.

⁴⁶ *Trans. Col. State Med. Soc.*, 1887, 59.

⁴⁷ *Lancet*, January 28, 1888.

⁴⁸ *Centralblatt f. Chirurgie*, February 1, 1888, p. 18.

⁴⁹ *Deutsche Zeitschrift f. Chirurgie*, Bd. 25, Heft. 3 and 4, 1888.

She was put to bed November 7th. During the continuance of her illness there were diarrhoea, scanty urine, slight tympanites, complete anorexia, so that at times food had to be poured down her throat, thirst, nausea, vomiting once or twice, mild delirium on a few nights, slight bronchitis throughout the entire fever, enlarged spleen, rose spots coming out once, and few in number.

Until the evening of November 9th the temperature was taken in the rectum, after that in the axilla on account of the nervous disturbance caused by the first method. The thermometers used were self-registering ones made by Hlicks, of London for Leach & Green, of Boston. On the morning of November 11th, the thermometer was broken before the temperature had been taken, and another could not be got till the evening.

	Morn.	Even.		Morn.	Even.
Nov. 7 . . .	104.8	105.8	Nov. 17 . . .	95.4	97.4
" 8 . . .	103.2	106.2	" 18 . . .	95.4	95.2
" 9 . . .	102.2	104.2	" 19 . . .	96	97
" 10 . . .	101	104.4	" 20 . . .	95.4	96.2
" 11 . . .	103.4		" 21 . . .	95.6	97.2
" 12 . . .	101.2	103	" 22 . . .	95.2	97.4
" 13 . . .	99.6	102.8	" 23 . . .	96.6	97.8
" 14 . . .	98.8	101.2	" 24 . . .	96.6	97.6
" 15 . . .	97.6	102	" 25 . . .	97	98.2
" 16 . . .	96.6	98.8	" 26 . . .	96.4	98.4

From this time the temperature did not drop below normal.

Through the period of low range of the thermometer beyond a slight irregularity of the heart's rhythm, the child developed no unfavorable symptoms, but gained steadily in strength, slept well, and eat in a satisfactory manner.

Is a period of thermometrical depression after typhoid fever common in young children, and unnoted because not looked for, or is its occurrence exceptional?

A CASE OF PELVIC ABSCESS. DEATH FROM HÆMORRHAGE.

BY E. T. HUBBARD, M.D., ROCHESTER, N. H.

A. W., aged thirty-four, married, had had several miscarriages; had been treated by a homœopathic gentleman for neuralgia of left hip, for two months previous to my seeing her. Saw her for first time November 11, 1887, found her suffering from severe pain in left hip, and lower part of abdomen. Pulse 120, temperature 103°, having night sweats, appetite poor, bowels constipated, urine normal in color, but scanty. Could get no history of abortion or injury. Upon examination found quite a large tumor in left inguinal region above Poupart's ligament, with obscure fluctuation. The vagina presented a hard indurated appearance and was bathed with a thick creamy pus which came from a fistulous opening in the posterior wall of the vagina just below the cervix uteri. I ordered hot poultices to be applied over lower part of abdomen and gave quinine and iron. At my next visit I found the patient more comfortable, temperature 102°, pulse 120; continued treatment for one week with the result of relieving her of all pain, temperature 100°, pulse 110; less swelling at night, but tumor increasing in size.

November 17th. Aspirated, and got about three ounces of thick yellow liquid, of the consistency of linseed oil. She got along fairly well with less pain

and a general amelioration of symptoms until December 18th, when the fistulous opening into vagina became closed, and pain began to be more severe.

Aspirated December 18th, and drew away about sixteen ounces of horribly offensive pus.

December 19th. She complained of pain in lower part of bowels, loss of appetite, and great wakefulness.

December 22d. Assisted by Drs. Daniel and Virgin, gave ether, and made incision just above Poupart's ligature in the middle of its course, as there was at this time a sense of fluctuation to be felt at this spot. After dissecting carefully, and separating the tissues by my finger more than the knife, keeping close to the inner aspect of the pubic arch, I reached the anterior wall of the abscess under the peritoneum. After making sure I had the abscess to deal with, by aspirating a little pus from it, I nicked it with the knife, and enlarged the opening with my finger. The pus gushed out in a horribly offensive stream to the amount of at least one quart, followed by a copious venous hæmorrhage from the interior of pus cavity. I placed compress above and applied a tight bandage which immediately controlled it. She rallied partially from the operation, but was taken with a chill which lasted one hour, being pulseless the most of the time, but under stimulants and external warmth, she rallied and passed a comfortable night. The next morning I removed the compress and washed out cavity with a solution of mercury bichloride, 1-2000. A few blood-clots came out at this time. I inserted a drainage-tube one-fifth of an inch in diameter by eight inches in length, and applied a pad of oakum to absorb pus.

I continued to wash it out daily with antiseptic solutions, the patient gaining strength, the temperature coming down to 98½°, pulse 100. Appetite good, slept well, and free from pain. I shortened drainage-tube until it was only three inches in length. On the fourteenth day after the operation, I had washed out the cavity as usual and found it growing smaller, and the discharge less in amount, and had flattering hopes of her ultimate recovery. While getting ready to introduce the drainage-tube I was horrified to see the blood spurt out in a bright red stream; I was surprised because there had not been one drop of hæmorrhage since the first day of the operation. I immediately passed my finger down into the wound which by this time had healed up to the size of the drainage-tube, and could feel the pulsations of the external iliac under my finger. I was then satisfied I had ulceration of this artery to deal with, as it lay close to the anterior side of the drainage-tube. As my experience with her in opening the abscess was anything but flattering, I did not deem it expedient to try to ligature the artery. I plugged the wound with absorbent cotton, knowing full well it was not a surgical procedure and also knowing that hæmorrhage would again take place, but I did not wish her to die under the knife, as I was almost certain she would if I attempted to ligature the external iliac artery. Hæmorrhage came on again the next day, and she finally died from exhaustion January 9, 1888. A peculiar feature in this case was to me that a patient suffering for nearly three months from pelvic abscess, should survive the operation for two weeks, and then die from hæmorrhage from ulceration of external iliac artery. This was the probable cause of death, though no autopsy was allowed. Possibly if the case had been taken in season it might have terminated more favorably.

Reports of Societies.

MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

Regular meeting, Wednesday, April 11, 1888.

Dr. P. C. KNAFF read a paper on

THE PHYSICAL DIAGNOSIS OF THE STOMACH IN DISEASE.¹

Dr. E. G. CUTLER said: I am very much interested in this subject, and am only sorry that I was called away so that I could not hear the whole of the paper, but the few concluding remarks that I heard lead me to say that Dr. Knapp has gone over the ground very thoroughly. I have tried for some little time these methods of examining the gastric juice in patients that have complained of gastric disturbance, and have been, on the whole, quite satisfied with it. It does not help us out to a very great extent, but it does somewhat, and the difficulty that I have found, and I have no doubt that Dr. Knapp has met with it also, in the majority of cases where time is an element of consideration; namely, dispensary cases, it is rather difficult to get patients to come a second time for examination, so that you cannot determine very readily about the character of the gastric juice after treatment.

I didn't hear what he said about the tests. The ones which I have used, and which have proved of the most service in my hands, have been the ones for the hydrochloric acid with tropæoline, and the methyl violet test, the ferric chloride and carbolic acid test, and recently I have been using the vanillin-phloroglucin test. I don't know whether Dr. Knapp mentioned that. I have found that rather better thus far than the others, although, with the precautions, and looking after the peptones, one can get along very well with the others. What he said about the necessity of pepsine I thoroughly agree with. It is quite rarely the fact that I give pepsin as we formerly used to do, in large quantities so many times a day; and I do turn more to hydrochloric acid, and, as he said, both Boas and Ewald have determined for us that the dose of hydrochloric acid is not usually sufficiently large.

I also agree to the fact that the so-called "nervous dyspepsia," in those cases which I have seen, have not shown any neurotic element that I could determine. My experience, of course, is not very large, but I have had several cases, and, as Dr. Knapp says, they were better treated by paying a little attention to their food and building them up generally. They always get along pretty tolerably well. I do not recall any case now that has not continued well. The first one that I saw was eight years ago, shortly after the disease was first written about by Leube, and that case has remained practically well ever since. She was treated almost exclusively without electricity, by other means, and has gotten along perfectly well. I had another case shortly afterward which has had several relapses, and is by no means well, who has these symptoms quite frequently. Another case that I had has passed out of my hands, and into the hands of an-

other physician. I understand, however, that it was for some other complaint that she was treated, and she appeared to be pretty well of the other trouble; at least it was not mentioned as a prominent symptom.

As far as the presence or absence of hydrochloric acid is concerned in cases of carcinoma, I have found it absent in cases which I believed to be carcinoma, but I have never had a case of autopsy, so as to prove it. I have found a very small amount in one or two cases which were believed to be chronic catarrh. In regard to the hyperacidity which Dr. Knapp speaks of, in cases where there is ulcer of the stomach, that has never come to my observation thus far. I have not seen a case of ulcer of the stomach for quite a long time, so far as I remember now. Certainly, I have no test of the juice in a case where I believed such a condition to exist. But I believe with him that it is an essential thing to do in some cases, and have not found great difficulty in persuading my patients to try it once, but I have met with difficulty in persuading them to try it more than two or three times, although I have now a patient whose gastric juice has been examined every week for some little time, who is improving constantly; but men, certainly in my experience, object to it less than women. Women do not seem to take to it very kindly. I have never met with any mishap in passing the tube, and take it. Dr. Knapp advocates the method brought forward by Ewald and Boas for getting the gastric juice.

Dr. KNAFF: For getting the gastric juice itself, I prefer Riegel's method.

Dr. CUTLER: That has the disadvantage of being rather dilute, and then, too, the question has occurred to me whether it would not be wiser for a person to use for the simple test just egg-albumen and little else. In that way, one eliminates the disturbing element of lactic acid which is usually found after Ewald's test breakfast. That is what I am doing now, using albumen as a food, and not the original test breakfast that they speak of.

Dr. FOLSON: There is one accident in using the stomach-tube which Dr. Knapp spoke of, and although the risk is not a great one, I think it is enough to be considered, so that some of the French physicians have devised various mechanical means to prevent it, one of which is to have a portion of the outside of the tube so made as to completely fill the esophagus. That danger is this: occasionally, at very rare intervals, the presence of the tube in the stomach causes very sudden and very violent vomiting, without very much warning. The food is regurgitated at once and without any apparent cause, and sometimes, after the patient has used the same tube a number of times, even without difficulty, and without the tube obstructing the natural movement of the epiglottis, it is very easy for some food to get into the larynx and cause inhalation-pneumonia. That has occurred a number of times. I don't know that it ought to prevent us from performing this test when it is necessary, but I can hardly believe that it is necessary so often as Dr. Knapp seems to think desirable; that is to say, I think, by paying very close attention to the clinical symptoms, we can relieve the symptoms without this danger.

There is another point, of which I have seen a number of cases, which is rather interesting, and that is dyspepsia, very obstinate and very painful, sometimes keeping the patient awake the whole night,

¹ See page 561 of the Journal.

without any very definite or ascertainable cause, and generally referred to some neurotic group of symptoms. I have seen quite a large number of these cases who have been through the hands of a large number of the profession, and who have had almost everything tried, and I have tried tonics of all sorts, and gymnastics, without relief of the trouble, and yet who are relieved by taking a very moderate dose of bromide of ammonium three times a day. It was a very great surprise to me to see the first case I treated. Since then I have used it in a number of cases, and I am convinced that there is a certain group of these neurotic cases which are not reached without something of the sort.

DR. CUTLER: I would like to ask Dr. Folsom if, in these cases of vomiting, the tube was not passed too far down.

DR. FOLSOM: I think not. One case occurred under my own eyes, where I was sure the tube was not in the stomach. I don't think it is a great danger, or can occur in a great number of cases, but it seems to me it is a thing to be thought of.

DR. CUTLER: I agree with Dr. Folsom, but it seems to me if a person is a little careful in the manipulation it would be very unlikely to occur. Of course, the fact that it has occurred would render it liable to occur again.

DR. KNAPP: In regard to that point which Dr. Folsom has brought up, I would say that it has always been my custom to pass the tube into the stomach.

DR. CUTLER: This for getting the gastric juice; but for feeding?

DR. KNAPP: Yes, for feeding I have always passed it completely into the stomach. I recall one case of very obstinate vomiting, where everything else had been tried. There had been some suspicion of malingering, but careful observation had convinced me that the man could not control his vomiting; he vomited everything that he was given, and nothing had any effect, except when we stood over him. Then he would not vomit for perhaps half an hour or an hour after taking the food, but during all that time there would be the constant retching and constant nausea, which was apparently very distressing; and he was finally fed by the stomach-tube — I didn't do it myself; it was after I went off duty — and after that there was no more vomiting.

DR. CUTLER: I think that is not a very uncommon occurrence for obstinate vomiting to be cured by the stomach tube. I have had it within a month in a case not so obstinate, where the person rejected food constantly. I would merely pass the tube down so as to be sure that it went into the oesophagus, and the food would stay. I have had a very few other cases. I don't say that it is not quite as well to pass the tube into the stomach, but it is not always necessary. That is what I mean to say.

DR. KNAPP: It is a way I got into in feeding by the stomach. I don't say that it is best, or that it is necessary.

DR. CUTLER: I have sometimes tried to have them stop, or swallow slowly, so that I could hear the food go in at the back of the stomach. I have tried all sorts of ways to do this, but I have never succeeded yet in making it slow in that way.

DR. FOLSOM: It is not necessary, Mr. Chairman, to pass anything into the stomach through the tube, because this violent vomiting is sometimes produced

by the simple presence of the tube itself, without passing anything into the stomach. If the tube is put in for experimental purposes, it will sometimes cause very violent vomiting, and with the tube near the epiglottis, it is very easy for food to get into the larynx.

DR. CUTLER: I agree that this may occur, but it should not deter a man from doing what is apparently necessary.

DR. FOLSOM: I don't think it should; but it seems to me that it should be used only after other means have been tried.

DR. VICKERY: I would like to say, as Dr. Folsom has, that I usually get out of gastric cases by a careful consideration of the symptoms, and such physical examination as I can obtain without these minute, careful, chemical tests. I believe that the stomach-tube is of great use in washing out the stomach in gastric catarrh, where it is very obstinate, particularly in drunkards, and a source of great relief to cases of cancer of the stomach, but I don't see how treatment has been revolutionized by the tests as to the fermentation or the nervous or muscular action, to be decided upon by taking out the gastric juice. I merely like to say this because, if we say that all these things are so necessary, it may discourage men in treatment, and I do see a great many stomach cases, and I think they get along very well. I am anxious to have chances to use the treatment; I have only one patient who uses it at present, and I think it does him a great deal of good. He was a drunkard. I have a case of cancer that I would like to try it in, but the lady objects. Dr. Gannett advises that if you once obtain consent, be sure to get the tube into the stomach that time, because you will never have another chance in the same person.

DR. J. A. JEFFRIES: It seems to me that one difficulty that has been made is that the tube is put too low down. Then the stomach walls may shut up on it, and you don't get anything. I have seen it tried, and thought the stomach was empty, and then, taking the tube out a little, have got plenty of juice. I think it is a point of some practical importance. There is one thing that comes in in speaking of diagnosis: if we don't wash the stomach out, and there is much mucus, the bacteria which cause fermentation are protected by the mucus and last over, but the normal amount of hydrochloric acid kills most of the bacteria, so that in animals or man, three or four hours after meals, the stomach is for practical purposes germ-free. In that way, I think washing out the stomach is a great thing in getting rid of these ferments, such as butyric and lactic acid. Of course, they do cause a good deal of distress. The easiest way to kill the bacteria is to wash the stomach out.

DR. CUTLER: From what I said, I did not mean that in every person who came to me with gastric symptoms I immediately introduced the tube and got the gastric juice. I try to get rid of the trouble in some other way, and if I cannot do that I may use these methods. I am unfortunate in not having heard what limitations the reader said; I heard him speak of the tube, and I took that. I should not wish to be understood as starting right off in this manner, because I don't do it. In fact, while I was on service at the Massachusetts General Hospital, this last four months, I think there were not more than four cases where the tube was systematically used. There was

one man, whom I think Dr. Vickery has now. Another fellow came in who had catarrh; I don't think that any of the others came in a second time. That is usually the case. I will say that I sometimes use it in the Hospital for my own experience, when I might not advocate it outside. The cases which need it are limited, but if a man once starts where it is really needed, it seems to me that there is nothing else that will supply its place.

DR. KNAPP: I would like to make practically the same statement that Dr. Cutler has. It certainly is a very disagreeable and rather laborious process to make a complete test of the gastric juice and the action of the stomach, and it is a thing that I admit in one or two cases I persuaded the hospital patient to allow me to do for the sake of my own curiosity; but certainly, in a great many cases of digestive disturbance it can be avoided, the patient may get on perfectly well, and you can treat them fairly satisfactorily. At the same time, there are a good many doubtful cases where it is an immense help, I think, and where the therapeutic use of the tube, which I did not lay any stress on, is one of our main resources.

(To be continued.)

CONNECTICUT MEDICAL SOCIETY.

THIS Society held its Ninety-seventh Annual Convention this year at New Haven, May 23d and 24th. There has been a growing feeling for some time past that the plan adopted for many years of having the Society meet alternate years at Hartford and New Haven should be so far modified as to admit Bridgeport as a third meeting-place, for there is no doubt but that the rapid increase of Bridgeport brings it close to Hartford in point of numbers, and, though not so central in location, it is only about thirty minutes from New Haven by rail. So confident were the Bridgeport members that a change would be made in this respect that they had a subscription paper numerously and generously signed, pledging a handsome sum to aid in the entertainment of the Society if its next meeting should be held there. But owing to the fact that a By-law stood in the way, which could only be altered by proposing the alterations one year and acting on them the next year, it could only be done by a suspension of said By-law by unanimous consent, and one negative vote settled the matter and left the *status in quo ante*. Consequently the meeting next year will be at Hartford.

The meeting was called to order at 3 P.M., by the President, DR. FRANCIS BACON of New Haven. This meeting is of the president and fellows, corresponding to the councillors of the Massachusetts Medical Society, only with the difference that any member of the Society may speak or introduce motions, or do anything but vote.

The committee on honorary degrees and membership reported for action the name of Prof. John C. Dalton, of New York, who was unanimously elected, and to lie over for one year under the rule, the name of Dr. E. M. Moore, of Rochester.

After some routine business the nominating committee brought in the following list, who were unanimously chosen.

President, Dr. G. L. Porter, of Bridgeport; Vice-

President, O. Brown, of Washington; Secretary, N. E. Worden, of Bridgeport; Treasurer, W. W. Knight.

Committee on matters of professional interest, Drs. L. B. Almy, L. T. Day, W. L. Ford; committee to nominate physicians to the retreat for the insane, Drs. M. Storrs and S. F. Risley; committee on publication, N. E. Worden and Dr. Almy; committee on arrangements, W. A. Wainwright, W. Bacon, E. R. Root.

Dissertator, P. H. Ingalls. Alternate, W. G. Brownson.

Delegates to American Medical Association, Dr. J. B. Kent, of Putnam, E. C. Kinney, of Norwich, C. H. Bill, of Bridgeport, H. B. Buel, of Litchfield, Dr. C. B. Newton, of Stafford, W. W. Welch, of Ansonia, S. B. St. John, F. D. Edgerton, of Middletown, B. W. Munson, of Noroton, F. E. Beckwith, of New Haven; to Maine, F. A. Merrill, and Ralph Goodwin; to New Hampshire, N. W. B. Dunham, and A. F. Douglas; to Vermont, H. G. Howe and S. G. Hubbard; to Massachusetts, F. M. Wilson and William Denning; to Rhode Island, F. L. Smith and E. S. Davis; to New Jersey, C. A. Lindsley and C. J. Fox; to New York, P. M. Hastings and H. P. Geib.

The so-called "New Charter Question," which appears now every year and is promptly voted down, was again brought forward, a committee appointed last year making a majority report recommending a slight increase in the number of fellows in the larger counties, and a minority report (supported by 4 out of 16 members) recommending the so-called new charter, sweeping away our present representative governing board. The minority report was suppressed by a vote of 24 to 12, and the majority report was also lost by 16 to 18. So we go on under the old dispensation for another year.

The Annual Convention began at 9.30 A.M. on Thursday. The evening before had been pleasantly spent at a microscopical soiree, held at the Yale Medical School, under the direction of the faculty, and at a reception later at the house of President Bacon.

The Secretary's Report showed an accession of 34 new names, and a falling off by death and removals from the State so as to leave a total membership of 494. A brief valedictory address was appended, as the secretary's resignation was handed in this year, after a service of five years.

The feature of the day was the President's Address to the Society, by DR. FRANCIS BACON. After a brief survey of the field of interesting topics which offered for a subject on such an occasion, such as recent improvements in the technique of surgery, local anæsthesia, advances in neurology, etc., the speaker announced his subject as

THE RELATION OF THE INSANE TO THE LAW IN THE STATE OF CONNECTICUT.

He made a powerful arraignment of the law as being meagre and insufficient. Here any "reputable physician certified to by any notary public or justice of the peace may certify his neighbor into confinement as being insane. In most other States this power is limited and restricted, requiring two physicians, graduates of some lawful school of medicine, having practised so many years, etc., not connected with each other in business, not connected by consanguinity with the person in question, not connected officially with any insane asylum, etc.

In this arraignment of the meagreness of the law, Dr. Bacon spoke as follows:

"A reputable physician!" What is a 'reputable physician' in the eyes of those august expounders and administrators of the law, the average notaries-public and justices of the peace? Perhaps some callow youth with the ink scarcely dry on the parchment which, with small outlay of time, labor, or cash, he has joyfully borne away from some diploma-mill, and eager to requite the low opinion that society has of him by condemning to confinement and civil disability some person with a clearer and steadier brain than his own; perhaps a chiropodist, perhaps a bone-setter, a 'magnetic healer,' a 'Christian scientist,' a 'faith curist,' a 'metaphysician,' a 'clairvoyant,' a 'theosophist,' any one of a hundred avatars of Belial or Moloch may be a 'reputable physician' before the all-embracing charity of our mother State. For my own part, when I reflect upon the extreme readiness of our laws to lend themselves to proceedings of this sort, and upon the momentous and far-reaching consequences of an act which is sometimes rather lightly performed, I respond to the not uncommon call for a certificate of insanity with more reluctance than attaches to most duties of the profession.

"If it is true, as I believe it is, that this dangerous power is but rarely abused to the detriment of citizens of Connecticut, it is so because, in this particular at least, our lives are better than our laws. The public, knowing the potentiality of many and various mischiefs that abide with the profession of medicine, is shrewd and quick to suspect misconduct in this business. The amendment of our law in this matter should be speedy; it is needed for the convenience and dignity of our profession to protect us from groundless accusations, even if it is not required for the safety of the citizen."

The speaker regretted the want of provision for a permanent commissioner in lunacy, and continued:

"I do not think that the State of Connecticut has acquired or deserved any special ill fame, as compared with other States of the Union, by reason of the abuse in her courts of the plea of insanity as a defence in criminal trials.

"Indeed, if such an accusation were brought against her, it might be repelled by quoting numerous cases of preëminent infamy from the judicial records of one of our nearest neighboring commonwealths, and a deplorably long array of others of similar character from some of the remoter States.

"Not yet in a Connecticut court have we seen the triumphant appearance of that illogical chimera of medical jurisprudence — 'transitory frenzy,' or 'acute moral insanity.'"

"Not yet have we heard a judge charge the jury all tremulous with compassion and stifling their sobs that they might listen to the words of wisdom, speaking with judicial authority, that the accused may have been of sound mind up to the moment of his aiming his deadly pistol, an irresponsible maniac when he pulled the trigger, and to have returned to sanity and mental fitness for good citizenship while the bullet was speeding to its mark.

"That appalling malady which seizes upon a man just before evocation in the ordinary quiet pursuits of some peaceful vocation, and in an instant reduces him to such a mental wreck that he may commit the highest crime known to the law without responsibility

therefor, and then as suddenly leaves him without any change in his normal condition except such as the unscientific might suppose to be the result of gratified vengeance, is as yet unknown to us here in Connecticut, save as we hear of by cases reported from other States illuminated by the latest discoveries in practical psychology."

The speaker then made running comments on the principal "somatic indicia" of insanity, some of which were quite sarcastic, and indeed there was a vein of humor running through the entire paper. He touched upon cranial lateral asymmetry, the unpleasant smell of the insane, bromidrosis and osmidrosis, the fibrillar tremor of the tongue, etc., and the so-called ophthalmoscopic signs, and in connection with the latter he gave an instance of a trial for murder where two physicians, one an expert neurologist, who relied largely on the ophthalmoscopic signs, had testified to the homicide's insanity. The plea of insanity did not avail, the man was sentenced to a term of imprisonment which he served out, and so far as heard from showed no insanity, while each of the two doctors certifying to his insanity, became an inmate of a lunatic asylum within a few months, one with violent mania, the other with a form of paranoia. Said he—

"As for the 'somatic indicia' at large, we may safely declare that the theorist who attempts to build up a case of lunacy out of any combination of them will find himself confronting from a different direction the conclusion which Polonius and many a philosopher since him, reached in his attempt.

"To define true madness
What is't, but to be nothing else but mad."

"The end of the matter is that the most expert of clinicians forms his opinion in any given case just as the unlearned do, on the basis of common sense, by considering the acts of the patient. If the ophthalmoscope and the sphymograph come in to confirm the opinion based upon the mental condition, well and good. Even such corroboration as may be had from those instruments of precision, the dynamometer and aesthesiometer, which falsely pretend to convert subjective symptoms into objective ones, may not be destitute of interest. The ankle-clonus, the knee-reflex, the cremasteric-reflex, the fibrillar tremors, the host of peripheral nerve phenomena that may be present or absent, will not be neglected by the careful student, and yet the fact remains that these somatic indicia may be present in abundance and variety and yet the subject of them may be of undoubted and active intellect,—they may be all absent and yet we may have to deal with a dangerous and incurable lunatic.

"I will go a step further and say: The physician on the witness-stand, who permits himself, under the manipulation it may be, of some wily and unscrupulous lawyer, to convey to a jury the idea that his means of determining the mental condition of any person in question, are different in kind, however superior they may be in degree, to those of the ordinary observer, puts himself in a false and untenable position, and fosters a fallacy already too prevalent. . . . It is beyond doubt or cavil that most of these frequent verdicts of not guilty by reason of insanity, are the expression, not of the judgment, but of the emotion of juries. They are due to a reluctance to award the full penalty prescribed by the law in cases where the crime is felt to have been to some extent an excusable, if not a justifiable act, of vengeance.

The jury, which is rarely logical but often sympathetic, feels a thrill of gratitude to the doctor who will say that his infallible ophthalmoscope or aëthesiometer shows the prisoner at the bar to be the hapless victim of irresistible cerebral disturbance. But is it right, is it even politic, for our profession to be carrying the opprobrium of what clear-headed and thoughtful men everywhere feel to be a trifling with the law and a setting at naught of evidence? In countries where, as in France for instance, it is permitted to juries to find that 'extenuating circumstances' mitigate the crime, the shameful absurdities of transitory frenzy and of insanity which is insanity *pro hoc vice*, for this occasion only, are unknown in the courts and conviction of high felonies and punishment, at least some substantial degree of punishment, are reasonably sure and speedy. But so long as our laws and our juries continue as they are, society will from time to time be exposed to the demoralizing spectacle of justice thwarted and crime shielded by the combined efforts of unscrupulous lawyers and of doctors whose lightest condemnation must be that they are ignorant or unreflecting."

In the following sentence the Massachusetts Statute is commended; but its effect is nullified by the power to pardon bestowed upon the Governor, of which he says:

"Pretty infallible, let us hope, the Massachusetts governor is, because under the provision of this last section, two years ago, to speak of only a single case, a man was turned loose upon society, who about six years previously had, not in a maniacal fury, but most deliberately, slain his own child in a way that curdled the blood of any one 'made of penetrable stuff' that heard of it. He had recovered his sanity, it was found upon inquiry, and accordingly was discharged. His insanity had been of that type which characterizes the truly sincere and devoted among the faith-curious, and which more commonly impels them to homicide by negation than to positive acts of violence. Admit that he had returned to a state of mental soundness, and still the question arises, what use has society for such a man? What better place can be found for him, taking his own view of it, than that where a humane and skilful custody has prevented his being a constant danger to himself and others?"

"What lapse of years, what painful assiduity in works of atonement, can ever make him less than an object of horror and suspicion to those about him?"

The paper concludes as follows: "Is it too much, then, to ask that every person acquitted of homicide upon the ground of insanity be declared permanently insane, and that he be for the term of his natural life subjected to such humane but efficient restraint as may be required to ensure both his own safety and welfare and that of society at large? I sincerely believe that a law to that effect would work no undue hardship to any one, but would be a substantial advance in the direction of practical justice and social safety."

The Society decided to raise a committee to go before the next legislature and advocate a law as recommended in the address. President Bacon appointed this committee as follows: Dr. Lewis, of Collinsville, Dr. Stearns, of Hartford, and Dr. Lindsley, of New Haven.

Resolutions of thanks to the retiring secretary, S. B. St. John, and treasurer, E. P. Swasey, were adopted.

GEORGE R. SHEPHERD, chairman of the committee on matters of professional interest in the State made an extended report. The subject treated was

ALBUMINURIA.

Extensive statistics had been compiled by the committee, from examinations made upon supposed healthy men. Some 35,000 examinations were collected from Life Insurance Companies, and some cases through the officials at Washington, when examinations were made before and after exercise, etc., and the following general conclusions were drawn:

(1) Albuminuria is much less frequent in the United States than in England, Stewart giving 31% as the general average, while ours, conducted upon a much larger scale, show but 2%.

(2) The brain-workers rather than the muscle-workers show the largest percentage of albuminuria.

(3) The urine of perfectly healthy people rarely shows albumen after food, while those who suffer from dyspepsia and oxaluria, are very liable to show it.

(4) Privation, scanty food and clothing with unsanitary surroundings, increase the liability to albuminuria.

(5) Cold bathing does increase the liability to albuminuria, though more notably so in case of dyspepsia.

(6) Severe exercise increases this liability in a very moderate degree.

(7) In the large majority of cases albuminuria is not associated with kidney disease.

(8) In the matter of Life Insurance, albuminuria should be looked on as a symptom only, and acceptance or rejection of the risk should depend on the gravity of the cause.

(9) The existence of any such condition as physiological albuminuria is extremely improbable.

This report, which was extremely elaborate, reflects great credit upon the committee, and especially on its chairman, who was peculiarly qualified to investigate this question, not only by reason of his experience as medical examiner for a great Life Insurance Company, but from the unusual facilities which his official position gave him for collating statistics. It is a report which will be extensively quoted in coming literature.

A paper on

PARALDEHYDE,

by DR. KENISTON, one of the physicians to the State Insane Asylum, gave the results of the trial of this comparatively new hypnotic. He gave it in drachm doses, sometimes repeating three times, and found it a reliable hypnotic in most cases of excitement and restlessness without pain, while free from the objections attaching to opium and chloral, leaving the patient bright and cheerful, not heavy and stupid.

DR. R. M. GRISWOLD, the Dissertator, read a paper advocating

CHLOROFORM AND EARLY USE OF FORCETS IN CASES OF LABOR,

as soon as the pains began to flag, or the patient to become in the least exhausted.

DR. C. W. RAY, of Vermont, DRs. A. M. SMITH and MOLONY, of Massachusetts, DRs. PALMER, and O'LEARY, of Rhode Island, were introduced as delegates from sister societies and spoke words of greeting.

Delegates to other Societies made short reports.

One of the most emphatic addresses of the day was that of DR. PARSONS, on

ALCOHOL IN THERAPEUTICS,

being a vigorous onslaught on those who would banish this article from our armamentarium because once in a while a latent appetite is awakened by alcohol medicinally advised.

DR. NEWTON's paper on

PNEUMONIA

dwelt especially upon the sharp contrasts to which we were exposed by keeping our dwelling-houses so hot in winter, as a cause for this dread disease. He also intimated that the formation of ptomaines might play an important part in the effects of this disease.

THE RELATIONS OF CARDIAC HYPERTROPHY TO NEPHRITIS.

was the title of a paper by DR. J. K. THACHER, Professor of Physiology at the Yale Medical School, a peculiarly able, though at first hearing, much-involved paper.

A CASE OF TYPHOID FEVER

with chart, showing the effect of antipyrine in lowering the temperature, was read by DR. G. C. SEGUR, and the time of adjournment was reached, leaving fourteen papers on the bulletin. Nothing could more clearly demonstrate the necessity for another session of the Society to hear and discuss papers. This we hope to have when the Charter agitation allows a chance for action in some other channels.

The Society adjourned and met at the New Haven House, where the annual dinner, and a very good one too, was served. DR. W. H. CARMALT, Anniversary Chairman, acting as master of ceremonies during the post-prandial exercises.

AMERICAN MEDICAL ASSOCIATION,¹ CINCINNATI, OHIO.

SECTION OF PRACTICAL MEDICINE, MATERIA MEDICA, AND PHYSIOLOGY.

SECOND DAY.—WEDNESDAY, MAY 9th.

H. C. VAN BIBBER, M.D., Chairman.

Election of officers for the ensuing year resulted as follows: Dr. F. C. SHATTUCK, of Boston, Chairman; Dr. G. A. FACKLER, of Cincinnati, Secretary.

Topic for discussion

DIAGNOSIS AND TREATMENT OF DISEASES OF THE STOMACH.

DR. WILLIAM PEPPER, of Philadelphia, opened the discussion with some practical remarks on the diagnosis of diseases of the stomach. To illustrate his points he cited a number of cases.

CASE I. A man had been losing two pounds in weight per week, for a period of sixteen weeks. No disease could be detected, blood and urine normal. No affection of heart and lungs. No enlargement of the spleen or glands. Eye ground presented no data of significance. No pain, vomiting and constipation. Teeth had failed and were hence an element of imperfect mastication. Careful diet with small doses of arsenic brought about a temporary cessation of flesh.

¹ Continued from page 554.

But emaciation in time resumed its progress. Only by excluding every affection demonstrable did the speaker arrive at a diagnosis of developing cancer in the walls of the stomach. The case resulted fatally three or four months after it was first observed by the speaker, and the walls of the stomach were found to be the seat of general carcinomatous infiltration.

Such cases demonstrate the want of something necessary to render a diagnosis accurate. Not only in cases so rare as this, but many cases will be met with in which one or two symptoms may be present, and yet the group is too inadequate to make a definite diagnosis.

The speaker had but recently seen a business man sixty-four years of age, who had previously enjoyed perfect health, but was suddenly attacked with some pain in the pit of the stomach, coming on when that organ was empty and at night. It recurred every night and extended from the pit of the stomach to the back. Bowels quiet or a little costive. He has lost thirty to forty pounds, pale but not cachectic. Most careful search of the epigastrium revealed nothing. Radials hard, arcus senilis present, abdominal aorta strong and appeared somewhat enlarged. No evidence of pancreatic disease. Under the use of careful diet, hydrocyanic acid, the application of the thermo-cautery to the region over the stomach and back a most remarkable improvement was noted. But it was only transient. Months passed and emaciation advanced, and a hardness could be detected close up to the crura of the diaphragm. Patient died and an autopsy revealed a fungus epithelioma in the superior and posterior walls of the stomach, doubtlessly involving nervous filaments in the dense adhesions. We recognize then, the need of something, outside of the clinical data as pain, vomiting, emaciation, etc., which although they usually suffice to establish a diagnosis, still fail when they are most needed for differential diagnostic points.

The speaker wished to allude to a field which seemed to offer us assistance in this regard; namely, the application of organic chemistry in the examination of the contents of the stomach removed in a systematic manner. Vomiting occurs so frequently, and the vomited matter is so mixed with portions of previous meal or with mucus, etc., that the study of the ejected substances is inadequate.

The contents of the stomach should be removed by aspiration. It should be done at a definite time after the ingestion of a definite meal, which shall consist of a certain amount of mixed food, starchy and nitrogenous. The matter obtained should be tested for free hydrochloric acid, lactic acid and peptic strength; that is, the power it possesses still further to digest albumen. The methyl violet is the best test for hydrochloric acid.

It is asserted by Riegel that in consequence of thousands of investigations, he has found that when cancer is present, no free hydrochloric acid will be found in the contents of the stomach six hours after a test meal. Here, then, we have a point of enormous importance, if it be established.

The secretion of the stomach is just as accessible as the urine. The statements have been confirmed by most excellent observers. The ability to diagnose accurately has distinct limitations. In our efforts to dignoscate a certain case some, or all, the classical symptoms may be absent. Here, then, a field has

been opened that appears to promise large results. What has been presented to us may be accepted as possessing confirmed value, although not regarded as infallible.

DR. F. C. SHATTUCK, of Boston, congratulated Dr. Pepper on the conservative position taken by him with regard to the inferences to be drawn to-day from the absence of free hydrochloric acid in the gastric secretion. Ewald has found that in some persons, apparently perfectly healthy, this acid is absent, and it must be kept clearly in mind that no diagnostic inference is to be drawn from one or two examinations. Such conclusions, if drawn at all at present, are to be based on the persistent presence or absence of the free acid. The phloro glucin vanillin test is probably the best; it is not only very delicate but apparently absolutely distinctive of hydrochloric acid.

Unfortunately, the quantitative tests are not so easy of application. The color tests are for this purpose entirely unreliable, and the method of Calm and v. Mering, demands in skilled hands one to two hours, a fact which puts its extended clinical use quite out of the question.

Dr. Shattuck then spoke briefly on hyper-secretion and hyper-acidity, with the relation of the latter to gastric ulcer, and of the great value of auscultatory percussion in defining the area of gastric resonance. The introduction of the soft stomach tube is rendered less disagreeable to the patient, if it is carefully washed from mucus, etc., after using. It is then perfectly smooth and requires only to be wet with water before being swallowed.

In closing, Ewald's salol test for the motor sufficiency of the stomach was alluded to. The speaker's experience with this test in about fifty cases of health and disease, led him to think that the number of healthy persons in whom upwards of an hour is needed after taking salol, before salicylic acid can be detected in the urine, with the solution of the perchloride of iron, is not very small.

DR. OCTERLONY had for several years made use of chemical analysis in the diagnosis of gastric disease. In no single case did the examination fail to corroborate the diagnosis. In malignant disease, free hydrochloric acid was always absent. Speaker referred to some symptoms which we are likely to meet with in malignant disease of the stomach; that is, hæmorrhage is of frequent occurrence, perversion of appetite is an early symptom, and a habitually lower than normal temperature comparatively early.

DR. WHITTAKER confined his remarks to the consideration of the presence or absence of free hydrochloric acid:

(1) Does the presence or absence of free hydrochloric acid indicate the presence or absence of carcinoma?

(2) Is the test easy of execution?

The general practitioner is not content with a method that demands execution by a chemist, but there can be no doubt that the test is easy of execution. A piece of Congo paper dipped into a solution of gastric juice is turned blue by free hydrochloric acid. It is a very sensitive test. Should there be any doubt, then apply the methyl-violet test. The patient should furnish the physician with the contents of the stomach. These are easily obtained. It is rarely necessary to employ the pump. The contents should be obtained seven hours after the ingestion of

a meal. Lactic acid is sought for by means of the carbolate-of-iron test.

Does the absence of free hydrochloric acid indicate cancer? On this point all seem unanimous that the persistent absence of hydrochloric acid, day after day, uniformly indicates cancer. The speaker did not mean universally, just as albuminuria does not universally indicate Bright's disease. The speaker was able to say conscientiously that in a period of five years he had never been deceived. The vomited matter is of no avail. The food which has undergone digestion for about seven hours should be withdrawn. If the symptom, absence of free hydrochloric acid, be established, and the patient be of the required age, no mistake can be made. What practitioner has not met with cases in which all symptoms were present, except the tumor? The absence of the latter rendered the diagnosis doubtful, but now the symptom under discussion clears up the case. Hyperacidity indicates ulcer. It is no more necessary to send the material to the chemist than to send urine for the detection of sugar or albumen. The intensity with which the Congo paper is colored points to the degree of acidity. An interesting point in this connection is that hyperacidity may cause ulcer, and also be the factor which prevents the healing of the ulcer.

A paper entitled

FOOD IN NERVOUS AFFECTIONS

was read by DR. EPHRAIM CUTTER, of New York.

THIRD DAY. — THURSDAY, MAY 10TH.

The session of May 10th was opened by the reading of a paper, subject:

SYRUP OF HYDRIDIC ACID IN GENERAL PRACTICE.

by W. C. WILE, of Danbury, Conn.

The form of remedy employed is the unalterable syrup presented to the profession in 1878. It has been the favorite remedy of the author in all asthmatic troubles, and has never been exhibited without unmistakable evidences of relief and comfort. Excellent results have been obtained in chronic bronchitis of long standing, chronic lead poisoning, scrofulous diseases, obesity, and in all the latest stages and manifestations of syphilis.

DR. J. McFADDEN GASTON read a paper on

CEREBRO-SPINAL MENINGITIS.

His object in preparing the paper has been to emphasize the great importance of recognizing the gravity of the situation at an early period by the general symptoms indicative of congestion, without waiting for indications of inflammation to determine the nature of the disease.

The author cited forty-five cases of meningitis, thirty-five of which were cerebro-spinal meningitis, and the balance spinal meningitis, with the following results: 80% of the latter and 40% of the former died.

As to treatment, the speaker thought that while the recourse to opiates has, in some cases, seemed to afford relief, it is evident that in most cases it only soothes the passage to the grave. There is an urgent demand for restoring the functions of the vital organs, and arousing the nerve-centres to action by revulsive applications externally, and revolutionary measures internally. Relying upon the special properties of a

mixture of calomel and quinine, he had employed it for the purpose of jugulating the progressive development of the congestive stage of this disease. Hot mustard baths were applied to the lower extremities, and cold to the head. Mustard plasters may also be placed along the spine, arresting or restoring the energy of the nervous system, and mustard applications to the inner portion of arms and legs.

The speaker cited cases in illustration and proof of the efficacy of this treatment, followed by salicylate of sodium and fluid extract of *Jaborandi*.

Dr. DIDAMA, of Syracuse, gave in detail

FIVE VERY OBSTINATE CASES OF HEMATURIA,

which, after resisting ordinary and extraordinary treatment for periods of from six weeks to three months, finally yielded in the course of a week or so to large doses of alum, twenty grains three times daily, or smaller quantities every three hours. He called attention to the importance of having the alum dissolved in a large quantity of water, and claimed that when so diluted—twenty grains to a goblet of water—it found ready access to the blood and urinary passages, and never produced constipation. Some of his cases had, under the care of the most eminent physicians, received the best known treatment without the slightest benefit. Alum had been used in some instances, but never in the large doses which he had employed with invariable success up to the present.

Dr. N. S. DAVIS had met with cases of persistent hematuria so severe as to greatly impoverish the patient and endanger life. He reported a case of such character which could not otherwise be explained than upon the theory that there existed a defect in the influence of the vaso-motor nerves over the vessels of the kidney. Acting upon this theory, the speaker had found the only remedies under which the patient recovered—ergotine on the one hand in moderately full doses, and, at the same time, the fluid extract of *hamamelis virginiana*. He disregarded largely astringent principles. It is probable that alum (advised in the paper), well diluted so as not to create gastric disturbances, will pass through the kidneys in sufficient quantity to increase the tonic of the kidney vessels.

Dr. G. W. McCASKEY thought that the majority of cases of persistent hematuria are due to an effusion of blood from the parenchyma of the kidney, otherwise to local lesions of the urethra, bladder, ureters or pelvis of the kidney. He thought that Dr. Davis's view was probably the correct one in many cases.

Dr. H. GRADLE, of Chicago, read a paper entitled

HEADACHES FROM OVERLOOKED CAUSES IN THE NASO-PHARYNX AND EARS.

He divided his cases into three classes, presented a full review of symptoms, and advised the appropriate treatment.

Dr. JOHN V. SHOEMAKER, of Philadelphia, read a paper, in which he took ground against the imputations that had been cast upon β naphthol.

Dr. V. C. VAUGHAN, of Ann Arbor, discoursed upon the

ETIOLOGY OF TYPHOID FEVER,

presenting in detail his experiments with the Eberth

bacillus obtained from drinking water, and the successful inoculation of dogs with the germ.

Dr. JOHN NORTH, of Keokuk, Iowa, read a paper on

SYMPATHETIC NERVOUS SYSTEM IN DISEASE.

SURGICAL SECTION.

THIRD DAY, THURSDAY, MAY 10TH.

THE SURGICAL ADVANTAGES OF THE BURIED ANIMAL SUTURE, AND ITS ADAPTABILITY TO SPECIAL PURPOSES,

by HENRY O. MARCY, Boston.

The introduction of antiseptic wound treatment has modified the use of the ligature to a degree which renders possible results hitherto never attained. Sir Joseph Lister's admirable researches on the animal ligature and the ligation of arteries, justly entitle him to the fame he has reached. The reader went on to say that these demonstrations and researches of Lister, although confirmed by other observers, were not applied to sutures until in 1871, when the essayist himself, in a case of strangulated hernia, freshened the edges of the ring and united them with catgut. Union speedily followed, and the cure was complete. From this experience and experiments conducted afterwards he established the operation for cure of hernia by aseptic suturing of the refreshed parts in open wounds. In this operation by means of the shoemaker stitch, devised by himself, the sac is stitched across and returned to the abdominal cavity. If it is too large a part of it is removed.

He has gradually extended the application of buried suturing, until he has treated wounds in nearly every part of the body by this method. In 1881 he applied successfully the same method to the stump of the uterus in hysterectomy. About the same time he used the animal ligature on the pedicle of an ovarian tumor, and reported the same at the International Congress in London, 1881.

Perineorrhaphy, laparotomy, plastic operations, etc., are all cases in which the animal suture is adaptable. In wounds that do not require drainage he is in the habit of burying even the superficial sutures by sealing them and the whole wound with an iodoform solution of collodion. The material used in buried sutures should be reliable and thoroughly aseptic. He prepares his own sutures from the tendons of the kangaroo. The ordinary catgut is not reliable.

There is no better test of the aseptic skill of the operator than in the introduction of animal suture. Septic material will easily be carried into the wound on the suture unless the surgeon follows strictly antiseptic precautions.

SARCOMA OF THE SCALP,

by P. S. CONNOR, Cincinnati.

In October, 1885, was consulted by Mrs. S., aged twenty-five, who stated that fifteen years before she had noticed a lump of the "size of a bean," not painful on pressure. At the end of thirteen years it began to enlarge, and continued to do so until the time of her confinement, five months before he saw her, when it was "large as a goose egg." Since that time the growth had been rapid and attended at times with severe pain. The tumor, occupying the occipital region, was, at time of consultation,

movable and apparently fluctuating. It was ellipsoidal in shape, its greatest circumference measuring twenty-one inches, and the least, at its junction with the head, fifteen inches. The mass was completely removed on the 23d of October, 1885, the rather profuse hæmorrhage being easily controlled by the application of hot water. The wound was dressed with iodoform. At the end of four days the drainage-tube was removed, and in eight days union was complete. The mass removed weighed five pounds, and was found to be a spindle-celled sarcoma. She continued well for eighteen months, when a small tender spot and soon after a hard lump was noticed. This continued to grow, until in March of this year it had reached larger dimensions than before, its greatest circumference being twenty-five inches. On the 3d of March, 1888, the tumor, together with portions of the pericranium, were removed, and the whole denuded surface touched with the Paquelin cautery. A mild erysipelas somewhat retarded healing, but in five weeks she was practically well. Weight of tumor, seven and one-half pounds. Patient was one month advanced in pregnancy when the recurrence was first noticed, and until the time of confinement the growth was very slow, this constituting one of the points of especial interest. The great size of the tumor, and the fact that primary sarcomata of the scalp are exceedingly rare, make this case of especial interest.

A recurrence of such growths may be expected, but an early operation when the tumor is first noticed as a hard lump in the scalp, will give to the patient the best chance for life.

INTRA-PERITONEAL RUPTURE OF THE BLADDER,

by H. H. GRANT, of Louisville, Ky.

Although indefinite reference to the propriety of attempting suture of the bladder after rupture is made by Gross, Larrey, Cusack, and others, and although Holmes, in his "Principles and Practice of Surgery," makes practical suggestions regarding this operation, yet up to 1886, Mr. Rivington declares in Heath's Dictionary, intra-peritoneal rupture, however treated, was almost uniformly fatal.

It appears that to Mr. Willett is due the credit of priority, and also of proposing the best style of suture for such injuries. In 1878, Mr. C. Heath, forty hours after the accident, closed an intra-peritoneal rent of the bladder with catgut sutures. Death, on account of extravasation, occurred on the sixth day.

An operation described by Pilcher in 1883, and successfully performed by MacCormac in 1886, is now recognized as possessing the best technique.

In a case which the essayist treated successfully, the patient, aged nineteen years, was run over by a cart, the wheel passing over the pelvis. By the use of the catheter, several ounces of bloody urine were withdrawn; this, together with the severe pain in the hypogastric region and the existence of shock, indicated intra-peritoneal rupture of the bladder, and laparotomy was advised.

The operation, antiseptic throughout, was performed about five hours after the occurrence of the accident. On opening the peritoneal cavity in the median line, a considerable quantity of bloody urine escaped. A loose fragment of bone, apparently from the horizontal ramus of the pubic bone, was found in the wound. A rent, two and a half inches long, was found in the fundus of the bladder, and this was carefully closed

with eleven sutures of carbolized silk, after the method of Lambert. The toilette of the abdominal cavity having been made, the wound was closed with deep silk and superficial catgut sutures. A rubber drainage-tube was introduced behind the bladder. Iodoform and dry antiseptic dressings were employed. At no time did the temperature rise above 100° F.; on the sixth day the tube was removed, and the convalescence was established on the fourteenth day.

The essayist presented a table of fourteen recorded cases of laparotomy performed for intra-peritoneal rupture of the bladder (including his own). Five of these recovered, and nine died. In a majority of these cases, abdominal drainage was practised after the operation.

The method of treating these intra-peritoneal lacerations by the plan of inaction will result in death in the large majority of cases, and he believes that a laparotomy, done with every antiseptic precaution, and a closure of the wound of the bladder by antiseptic suturing promises the best possible chance of recovery to the patient. When the wound in the bladder wall is irregular, much lacerated, and the general conditions of the patient are unfavorable, the method of stitching the edges of the vesical wound to those of the wound in the abdominal wall may be adopted. The wound in such a case could be stuffed with iodoform gauze, and drainage could be effected through a tube and also a catheter.

The importance of an early diagnosis and an early laparotomy should be recognized. The history is usually clear, and the symptoms prominent. Severe pain, accompanied by great desire, but fruitless efforts to urinate, are symptoms that are suggestive. The urine that is withdrawn is bloody. As to the after-treatment, he thinks that the advantages to be gained by catheterization, thus preventing any distension of the bladder from an over-accumulation of urine, far outweigh the dangers of its careful use. The viscus should not be allowed to fill, but after four or five days the patient may be allowed to pass urine in the natural way, avoiding all straining.

DRY MEDICATION IN THE TREATMENT OF URETHRA AND BLADDER,

by ELMER LEE, St. Louis.

By the use of granules of cane sugar, in which may be incorporated any medicament, such as an alkaloid, and which are introduced into the inflamed urethra, bladder, or uterus, he claims that the treatment of diseases of these organs may be much more successful than hitherto. The granules, which vary in size and dose to suit individual requirements, when placed in the urethra, dissolve in the mucus of the part, allowing the medicament to come in contact with the inflamed area. The instrument for introduction of the granules consists of a tube or catheter, with the eye at the end. Through this the granules are pushed by means of a probe. The claim is made that these pellets are not so irritating as gelatine bougies or other urethral remedies.

AN ANTISEPTIC SURGICAL CABINET,

by H. LANDIN GETZ, or Marshalltown, Iowa.

The expense of preparing a special room in which to perform laparotomies, ovariectomies, etc., and the time required to put such a room in an aseptic condition, prompted him to devise the cheap and efficient

substitute which he exhibited to the Section. It consists of a framework of light wooden poles, which support a covering of cheese-cloth, which falls to the floor on every side. This cloth, before being placed over the frame, is wrung out of a strong bichloride solution, and is presumed to intercept all germs from entrance to the operating cabinet. The gauze on one side is fastened to the wall around a window, so that the latter forms one wall of the little apartment, and admits light. An antiseptic spray can be kept playing on the gauze to keep it moist all the time during the operation. The operating table is so placed that the head of the patient may be on the outside of the cabinet, while the cloth forming that side falls to each side of the table like a curtain. The instruments may be handed to the operator through the flap door at one side.

His claims for the device are that it is simple, inexpensive, and easily constructed. The air within it may be readily purified by the antiseptic spray, while the air that enters from without is rendered aseptic by coming in contact with the bichloride solution in the gauze walls. The patient's head being outside the tent, the attention of the assistant administering the anæsthetic cannot be distracted from his work, for he cannot see the field of operation.

DR. VAN HOOK, of Chicago, wished to call attention to the fact that Dr. Prince, of Illinois, has used for his abdominal operations a room supplied with air which has been rendered thoroughly aseptic by passing through some disinfecting process. But it is not possible to keep the atmosphere of an apartment aseptic, for enough germs, morbid and non-morbid, are exhaled by the operator and all in the room to thoroughly contaminate it. As to the cabinet of Dr. Getz, he feared that the meshes of the cloth were too large to prevent the entrance of germs.

WOOD-FIBRE AS A SURGICAL DRESSING,

by J. W. BROWN, Mattville, N. J.

Dr. Brown was not present; his paper was read by title.

(To be continued.)

Recent Literature.

Pulmonary Consumption; Its Etiology, Pathology and Treatment. By C. J. B. WILLIAMS, M.D., etc., and CHARLES THEODORE WILLIAMS, M.D. Second edition, enlarged and rewritten by Dr. C. THEODORE WILLIAMS. Philadelphia: P. Blakiston, Son & Co. 1887. pp. 431.

The appearance of a new edition of this well-known work affords a good opportunity for a review of the advances in our knowledge of consumption since 1871, the date of publication of the first edition. To pass over minor points, the two directions in which progress has been made are in pathology and in climatic treatment. The experiments of Villenin in 1861 first gave a scientific basis to the idea that consumption is an infectious disease, and the work to which these experiments gave rise culminated in Koch's great discovery which has so cleared up the vexed question of the pathology of tuberculosis that the ninety pages of conflicting views in the first edition

shrink to fifty, mostly of established fact, in the second. A comparison of the chapters given to pathology impresses strongly upon the reader the magnitude and importance of the revolution which has been worked.

Secondly, the high altitude treatment of consumption may be said to have been born, and even come of age in the years since the first edition was printed. At present the remarks of the author on this subject are general in character, though he discusses briefly the indications for and against the choice of a climate by this class for individual cases, but he strongly hints on page 369 that we shall ere long have the benefit of detailed results of his large experience with mountain stations.

On page 59 the author seems to maintain the view that tuberculosis itself, like syphilis, is inherited, and cites as disproving the position of Virchow and others a passage from Seydlamore, who examined the body of a child dying greatly emaciated at four months, and found a general tuberculosis. The mother was advanced in phthisis when the child was born. We cannot see that this case proves anything. It seems vastly more probable that the child was congenitally predisposed to entertain and breed the bacillus, which, however, entered the system after birth, coming from the air passages of the mother. While we are not in a position absolutely to deny the possibility of the hereditary transmission of the disease itself, the weight of evidence at present is certainly against such a possibility. It will be interesting and instructive to see whether Jani's observations are confirmed. He claims to have found isolated tubercles in the otherwise healthy vesicular seminales and prostates of consumptive males, and also in the folds of the mucous membrane of the tubes in females.

We regret that the author has not thrown the light of his experience on the question of the existence and frequency of simple pleurisy due to exposure to cold; it is held by many authorities now that such an affection is very rare, if it occurs at all, these pleurisies being really tubercular from the start.

To show the position of the author toward prognosis and treatment, the following passage from the preface may be quoted: "The outlook of the future of consumption is decidedly hopeful, for there is little doubt that much of the disease is due to preventable causes, which the coming reign of hygiene will sweep away, and that in many cases the disease will be nipped in the bud by a combination of anti-phthisical and bacillicide treatment, while, in more advanced cases, life will be prolonged even beyond its present lengthened duration."

Of course a direct bacillicide treatment is not at present known to us.

We are somewhat surprised at a statement on page 341 with regard to milk, which "is of such vital importance to the consumptive that some form of it must always be insisted on. But two cautions are necessary; one, that it must never exceed one quart a day, and that if cod-liver oil is taken the quantity shall be limited to a pint." Our experience here in America does not at all coincide with the above. We find that patients can take and digest, without impairment of appetite for other things, larger quantities of milk than Dr. Williams thinks desirable to administer.

There are many other points which we should like

to note, and very many which we should like to commend, did space permit. If the profession does not keep abreast of the advances in our knowledge of consumption it is not the fault of Jaccoud, Scé, Powell and Williams, new works, or new editions of works by whom, on consumption, have appeared, and been noticed in these columns within the last few years.

F. C. S.

Abdominal Surgery. By J. GREIG SMITH, M.A., F.R.S.E., Surgeon to the Bristol Royal Infirmary, etc. Philadelphia: P. Blakiston, Son & Co. 1887.

This book of six hundred pages is an attempt to describe in a systematic manner surgical operations of the abdomen. The recent rapid advance in this department of surgery, and the immense collection of data, the result not only of increased clinical experience, but also of valuable experimental research, which is now scattered haphazard in a wilderness of periodicals and monographs, necessitates a concise review of the subject. There is no other work in English in which detailed descriptions of the various procedures authorized by modern surgery are collected; hence a systematic rearrangement of these facts and methods, which have been proved by experience to be the best in this most trying class of cases, is especially valuable and useful, and any one who has been compelled to search through the mass of current literature now at hand to learn the most approved technique for some abdominal operation, or the most successful method of treatment, will appreciate at once the true value of Mr. Smith's work. The volume is clearly written, and is the presentation not only of the results of bibliographical research, but also an exposition of knowledge gained from actual experience. The author can be said to a certain extent to have practised what he preaches, and states what he himself believes, instead of giving, as is so often done, merely a compilation of the opinions of others.

"Treatment by operation" has been his motto. Normal and pathological anatomy, histology, and clinical history are introduced only so far as they have a direct bearing on diagnosis or treatment. Thorough and complete asepsis is conspicuous. The description of operative technique is the chief feature of the book, and all the principal operations involving the stomach, intestines, liver, gall-bladder, kidney, spleen, pancreas, ovaries, broad ligaments, and the gravid or unimpregnated uterus, are here given in detail. The remarks relating to the treatment of patients subsequent to operation contain many valuable suggestions. The author's views are usually clearly stated, and although, perhaps, not in every instance in accordance with those held by the most prominent surgeons, still are seldom without some good reason for their adoption. As a rule, the book seems a reliable one, but at times an incongruity of statements shows a rather careless style.¹ This is apt to induce a certain amount of caution in accepting the author's statements as always absolutely accurate. The book is a compendium, not a complete work on abdominal surgery. This is what the author intended, and he deserves the credit of having made a valuable contribution to surgical literature.

¹ Page 131: "Primary cancer of the ovary is rare." Ibid: "Primary cancer also frequently attacks both ovaries." Page 191: "On the operating table the proceeding" (vaginal hysterectomy, an operation at times a most trying and difficult one) "ought not to occupy more than a quarter of an hour."

THE BOSTON Medical and Surgical Journal.

THURSDAY, JUNE 7, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE ONE HUNDREDTH AND SEVENTH ANNUAL MEETING OF THE MASSACHUSETTS MEDICAL SOCIETY.

The approaching annual meeting of the Massachusetts Medical Society will present some rather unusual features. The papers give promise of unusual merit and the subjects are for the most part of general interest.

Among the items of business a report will be expected from the committee appointed at the last annual meeting to investigate the subject of Physical Culture in the Schools, and the matter of amending the conditions of admission into the Society, already acted upon by the Council, will be brought up. This latter item is of the greatest importance. The proposition is to permit the examination for admission to the Society by the Censors of the graduates of certain irregular schools. At the present moment a man who has taken a degree from a school not classed as regular can find no means of admission to the society save by the acquisition of a degree of one of the accepted schools. Occasionally a man presents himself who is fully qualified for membership and is desirous of admission but does not care to go back to school again in his advanced years. The proposed change is to meet such individual cases. The measure so far recommended itself to the Council as to pass that body without a dissenting vote.

The usual banquet will loose many of the features which have become inseparable from it in the minds of the members. The impossibility of securing a proper hall for the dinner has obliged the change to a less formal, but probably equally enjoyable meeting at which no one need lose his dinner but which will permit free circulation and the interchange of ideas with friends and acquaintances.

How popular such a gathering will prove in comparison with the formal tables and set speeches of previous years it is impossible to foretell. Certainly it will for once prove a novelty and we trust a pleasing one.

THE PHYSICAL EXAMINATION OF THE STOMACH, AND THE VALUE OF THE ABSENCE OF FREE HYDROCHLORIC ACID AS A SIGN OF CANCER.

IN the present number of the JOURNAL we publish a report of two interesting discussions upon the diagnosis and treatment of diseases of the stomach, one of which took place before the Section on Practical Medicine of the American Medical Association, and the other before the Section on Clinical Medicine of the Suffolk District Medical Society. It is hardly an exaggeration, we believe, to say that no subject presented at the meeting of the American Medical Association exceeds in importance this of the physical examination of the stomach as a means of diagnosis and treatment. The methods by which we can now determine the chemical composition of the gastric juice and the functional activity of the stomach give us, at last, objective data in regard to gastric diseases which before were lacking. Of the value of such data in diagnosis there is, of course, no question, and these new methods of examination of the stomach, which we owe entirely to the Germans, are of as much importance for the diagnosis of gastric disease as is the examination of the urine for the diagnosis of renal disease, or the use of the stethoscope for thoracic affections. The disagreeable features attendant upon such an examination will naturally act as a check to its general adoption, and many physicians will content themselves with making a diagnosis without a resort to the stomach-tube. In certain cases of phthisis, or Bright's disease, or tabes dorsalis, we may feel reasonably sure of the diagnosis without resorting to a careful physical examination, and the same may be said of many cases of gastric disease; but there are many other cases, like those reported by Dr. Pepper, where we gladly welcome anything that will give us new light. Such light will, we believe, be furnished by the German methods of investigation, and the men who have used them the most are the firmest believers in their value. Certainly, in the short time they have been in use, our knowledge of the diseases of the stomach has been so much increased, that in no other subject in medicine, except in bacteriology, have so great advances been made.

The most important question which is to be determined by the chemical examination of the gastric juice—but by no means the only one, as some seem to think—is in regard to the presence or absence of free hydrochloric acid, and the chief point in dispute at the present time is in regard to the absence of hydrochloric acid in cancer of the stomach. Dr. Shattuck has done well in calling attention to the fact that we must not rely upon one or two observations. Only the constant absence of the acid is of value. The question of the absence of free hydrochloric acid in cancer is still in dispute, but in the great majority of cases thus far reported the ordinary tests—methyl-violet and phloroglucin-vanillin—fail to give the reactions. Certain observers, among them Rosenbach and Germain-Sec,

have found the acid by the ordinary tests in a few cases of cancer, and more elaborate tests performed by Cahn and Von Mering have shown that there is hydrochloric acid, either free or in unstable combination, in cases of cancer examined by them. Nevertheless, the absence of free hydrochloric acid, although not absolute evidence, is a sign of great value in diagnosis. Dr. Whittaker's comparison of this sign with albuminuria is suggestive. Albuminuria is certainly a sign of great value in the diagnosis of renal disease, but it is not pathognomonic of such a disease, nor is it always present. In the same way, it is probably true that free hydrochloric acid is not always absent in cancer of the stomach, although it is absent in the majority of cases, and, furthermore, when hydrochloric acid is absent, it is not pathognomonic of malignant disease. This latter point has been overlooked by some of the recent writers on the subject, but the pioneers in the field, notably Riegel, have repeatedly called attention to the fact that there were various affections of the stomach in which free acid may be persistently absent, and Ewald has noted its absence even in health. It is, therefore, assuming too much to claim that its absence is pathognomonic of any one affection.

We must still hold a judicial position with regard to these new methods of examining the stomach. They have already done much to advance our knowledge, and will undoubtedly do much more, but it is the part of ignorance to rely upon single examinations, or to claim a decisive value for any single test. Repeated examinations, not only of the chemical composition of the gastric juice, but also of the various functions of the stomach, added to the methods already employed, will give us most valuable information both in the way of diagnosis and treatment. Single tests for this or that sign will in this, as in all other classes of disease, lead to unbalanced and erroneous judgments.

ON THE TREATMENT OF PHTHISIS PULMONALIS BY SOJOURN IN ELEVATED CLIMATIC STATIONS.

AT the recent meeting of the Royal Society of Medicine and Surgery (May 8th), Dr. Theodore Williams read a paper on the above subject, and indicated the results which he had obtained in a series of 141 cases.

These 141 patients, all of whom had been under observation during the last nine years, were sent to various stations of the Alps, of the Rocky Mountains, and South Africa. The altitude of the stations varied between 1,500 and 1,700 meters. The average length of time during which the disease had been progressing before the beginning of the treatment was about two years; sixty-one patients had had hæmoptysis, and four of these were cases of true hæmorrhagic phthisis. The mean age of the men was twenty-seven years, and of the women, twenty-four years. Ten patients had fever at the time of their departure; ninety-one were

in the first stage, and fifty in the second or third; seventeen per cent. only of the cases could be classed as incipient phthisis.

In fifty-three cases both lungs were affected, in eighty-eight only one, and the left oftener than the right. The presence of the tubercle bacillus was detected in the sputa of fifty-four patients, but it is only recently that such examination has become the rule. These patients had all been previously treated by tonics, cod-liver oil, etc.

When once the patient had arrived at the station where he was to reside, he was required to take daily walks on level ground; later on, skating, tobogganing, and mountain climbing was allowed. During the spring thaws, the patient was advised as a general rule to quit the Engadine, while, if in Colorado and South Africa, he might sojourn the year round in the mountains or on the elevated plateaux.

These are the results which Dr. Williams claims to have obtained: the proportion of complete recoveries has been 41.13 %. In 29.78 % there was considerable improvement, in 13.47 % slight improvement; 17.02 % were made worse by the change; there was a mortality of 13.47 %.

From the point of view of the local symptoms, an amelioration was noted in 74.82 % of the cases; in 3.59 % the condition remained unchanged; in 21.5 % there was an aggravation. As for the cases in the first stage of the disease, the proportion of ameliorations to cures was 91 %; in the later stages, this proportion was 46 %.

From these statistics, the writer draws the following conclusions:

(1) A prolonged sojourn in elevated climatic stations produces an amelioration in the majority of cases of phthisis pulmonalis; it may arrest the disease temporarily or permanently in many cases.

(2) It is useless to expect a favorable result unless the patient be free from fever and acute symptoms, and unless there is sufficient healthy pulmonary surface to enable respiration to be well performed in a purified atmosphere.

(3) It is seldom that the state of patients remains stationary during the sojourn in elevated regions; you note sometimes an improvement, sometimes an aggravation.

(4) The circumferential chest measurement augments from two to ten centimeters during the treatment. There is produced a considerable hypertrophy of the healthy pulmonary tissue, and more or less emphysema around the tuberculous lesions; the expansion of the thorax is accompanied by a diminution in the frequency of the pulse and of the respiration.

(5) The arrest of the disease is probably due, in part, to the compression exercised on the tuberculous lesions by the augmentation of volume of the surrounding tissues.

(6) In proportion as the local symptoms disappear, there is an amelioration in the general condition; the patient increases in weight, has a better color.

(7) Phthisical patients of both sexes equally profit by sojourn in elevated stations; as far as age is concerned, the results are less satisfactory in women before the twentieth year, and in men before the fortieth.

(8) The results are especially favorable in cases where there exists a hereditary predisposition.

(9) Mountain climates are useful in hæmorrhagic phthisis, and diminish the tendency to hæmoptysis.

(10) The arrest of the disease is the more probable the more recent the lesions, but an improvement is often noticed in old cases.

(11) The special influence of sojourn in elevated regions is observed at all altitudes above 1,500 meters.

(12) In the majority of cases, the duration of this sojourn should be six months, at least.

(13) Mountain climates are useful not only in phthisis, but in other affections, such as incomplete development of the lungs and of the thorax, chronic bronchitis without bronchiectasis, pulmonary retraction after chronic pleurisy, spasmodic asthma not accompanied with notable emphysema, and in anæmia.

(14) Mountain climate is contraindicated in the following cases: (a) tuberculosis with bilateral cavities, with or without fever; (b) phthisis with considerable diminution of the respiratory surface; (c) catarrhal phthisis; (d) phthisis with considerable irritability of the nervous system; (e) emphysema; (f) chronic bronchitis with bronchiectasis; (g) affection of the heart, of the large bloodvessels, or of the central nervous system; (h) advanced age, or a state of feebleness too great to allow exercise in the open air.

In the discussion which followed, Dr. Hermanu Weber stated that he had notes of 106 cases similar to those of Dr. Williams, and he had arrived at almost identical results; namely, 40 % of cures, and about 40 of amelioration. Of the 106 patients, 70 were in the first stage. In response to a question of Dr. Haviland Hall, Dr. Williams said that laryngeal phthisis was unfavorably influenced by mountain climates.

Dr. Pollock said that he had treated more than 13,500 cases of phthisis in the Brompton Hospital, and his impression was that Dr. Williams's cases were precisely those that *might* get well or improve in London, as elsewhere. If you send to the mountains only patients who have no acute symptoms, no fever, it is not astonishing that you get good results; the absence of fever in phthisis pulmonalis is always a favorable sign. Chronic tuberculous patients who have not passed the first stage often get well in London, and as for cases where there is only one cavity in one lung, these often remain stationary, even in England, for twenty-five or thirty years. We have heard of the gout of the rich and the gout of the poor; there is also a phthisis of the rich and a phthisis of the poor, and it is to the first only that the remarks and statistics of Dr. Williams apply.

Dr. Jucker Wesi, of Maloja, Engadine, remarked that the air of the Alps produces, in a very short time, a favorable effect on the appetite. The cold, aseptic

air exercises a sedative action in the bronchial mucous membrane, and diminishes the cough. It is probable that the ozone contained in the air plays an important part, and that the solar rays, to which the patient is almost daily exposed, favor the transformation of leucocytes into red globules. It is interesting to note that patients who sweat easily do not experience the dyspnea which often appears at the commencement of a sojourn in high regions.

The facts and conclusions above given by Dr. Theodore Williams, and confirmed by the experience of Dr. Hermann Weber, strikingly coincide with those of Dr. F. I. Knight in his paper lately read before the Boston Society for Medical Improvement, and published in this JOURNAL, April 5, 1888.

MEDICAL NOTES.

—The health-officer of San Francisco wrote to the health-officer of New York under date of March 20th, as follows: "Yesterday Anton Anderson, aged twenty-one, a native of Norway, was sent to the small-pox hospital. He stated that he came from Glasgow by the steamship *Cirassian*. Immediately on landing at New York he left for this place, arriving here on the 17th instant by the Southern Pacific railroad. According to his account he was taken sick on the 11th, the eruption appearing on the 14th. It is a bad case of confluent small-pox."

A San Francisco paper says: "The steamship *Main*, from Bremen, which had been detained at quarantine for two days on account of a case of small-pox being discovered on board, reached Pier 8, Locust Point, Baltimore, yesterday. Her 1,147 emigrants were discharged and sent west by the Baltimore and Ohio Railroad. That is the way they do it in the east. On this coast she would have been kept in quarantine about a month."

—Dr. Paul F. Mundé, at the request of the Faculty of Dartmouth Medical College, has consented to deliver the course of lectures on Gynecology at that institution this year, beginning July 13th, it being found impracticable otherwise to fill the vacancy caused by the death of Dr. Dunster. Dr. William H. Parish, of Philadelphia, will give the course of lectures on Obstetrics this year.

—Prague, with a quarter million of population, treats 7,000 in-patients in her hospital and 50,000 outdoor patients, while the incomes of the medical practitioners are growing very small, according to a letter in a foreign contemporary, which says that "a large number of Bohemian practitioners are now making less than £100 a year, with a prospect of a still further diminution of their income in the near future."

—The very rare phenomenon of six at a birth occurred in the first week of May last says, the *Lancet*, at Castagnola, a village in the neighborhood of Lugano, on the Italian-Swiss frontier. The wife of the

Syndic (Mayor, as we should call him) brought forth at a birth six children, four males and two females, all of whom died shortly after, while the mother made a good recovery. Her name is Filomena Rezzonico; she is thirty-eight years of age, and has already given birth to seven children after only two confinements, four being born at one delivery and three at another. Her husband, the Syndic, by his former wife had ten children, of whom seven survive. A note with comments on the case, will shortly be published by a well-known gynecologist of Milan.

BOSTON AND NEW ENGLAND.

—At the annual meeting of the Massachusetts Medical Society next week, the usual formal dinner is to be replaced by a reception at the Vendome, which will afford an abundant scope for the social instincts of the members. We advise the members, instead of overloading stomachs and carpet-bags with the appetizing dietetic and pharmaceutical preparations which are so freely offered, to enter the hall and listen to the papers. The general list of papers is far too attractive to be read to empty seats. Come in, gentlemen, and encourage by your presence those who have spent time and care in working up their articles.

—The house recently occupied by Mrs. Robinson, of Somerville, who was convicted a few months ago on circumstantial evidence, of the murder by arsenical poison of one of her relatives, and who is supposed to have been guilty of other similar murders, has lately been occupied by a new tenant, who, in making repairs, discovered in the cellar a package of "Rough on Rats." An occupant intermediate between Mrs. Robinson and the present tenant avows that he never had any of the poison, and while it is possible that it was there before Mrs. Robinson's occupancy of the house, it is believed by the police that she used it in accomplishing the murders.

—Mrs. Kate Gannett Wells, chairman of the executive committee, and Miss Ellen M. Tower, Secretary, of the Massachusetts Emergency and Hygiene Association, gave a reception last week in honor of Miss Clara Barton, President of the "American National Red Cross," from whom the Emergency Society derives permission to use the insignia of the Red Cross. That cross, enclosed in a triangle, the triangle symbolizing the Esmarch handkerchief bandage, is used on all the documents and certificates of the society. The reception was largely attended by members of the association, and by others interested in the work, and was a pleasant occasion.

NEW YORK.

—At a meeting of the Medical Society of the County of New York, held May 28th, Dr. John C. Peters read a paper on "The Water-Supply from the Croton Lake System," in which he stated that the sewage created by 25,000 people, the largest condensed milk factory in the world, 10,000 cows, 1,200

horses, 1,500 hogs, and 40 factories, was all being run into that body of water from which the city of New York draws its water-supply. While in former years the Thames water used by London contained five times as much bacteria as Croton water, recent investigations showed that in one cubic centimeter New York water contained 526 bacteria, against 44 contained by London water. While, of course, the greater part of these were the common, harmless bacteria, still there was a large proportion capable of producing disease, and he expressed the opinion that a great deal of the scarlet fever, diphtheria, and other infectious disease which prevailed in New York might be traceable to germs derived from the water-supply.

A resolution was offered by Dr. Peters, and unanimously passed, calling for an official examination of the present condition of the waters of Croton Lake, and urging that such steps should be taken by the authorities as should be deemed advisable to ascertain if the works now being constructed will deliver to the city the "pure and wholesome water" referred to in the terms of the act creating the present Aqueduct Commission. Copies of the resolution were ordered to be sent to the Board of Health and the Department of Public Works, and when the resolution was received by the latter, the matter was at once referred to the Chief Engineer for a report. While it is probable that the efforts of Dr. Peters may excite unnecessary alarm in the public mind, it is, of course, of the utmost importance that the condition of the water-supply should at all times be the subject of the greatest possible care, and such concerted action on the part of the medical profession will no doubt have a good effect in stirring up the public authorities to a proper state of vigilance.

—Among the bills recently signed by the Governor, is one which provides for matrons in the police stations in the cities of the State, and also for a sufficient accommodation for women under arrest, separate from the apartments for males.

Miscellany.

MYOSITIS OSSIFICANS.

DR. LENDON, of Adelaide, has recorded in the Transactions of the First Intercolonial Medical Congress, August and September, 1887, says the *Lancet*, the particulars of a case of this very rare disease.

The man died at the age of forty-six, having first shown signs of the affection when only eight years old; but he had always been clumsy with his right arm and forearm and, as during boyhood the stiffness increased, it was attributed to injuries received at various times. He became greatly deformed, with bent rigid back and limbs, and before his death he suffered from numerous bed-sores, and was reduced to a pitiable state. Many muscles were partially or wholly converted into bone, notably both latissimi, which caused the scapulae to be firmly fixed to the thoracic cage. In the limbs the joint surfaces were fairly

normal, or the cartilages in fibroid degeneration, although the joints were greatly surrounded by irregular masses of bone due to ossification of muscles and ligaments. The spinal and costal ligaments were all ossified, making the back quite rigid. Dr. Lendon also quotes an interesting description of a similar case from a work on the city of Cork, by Charles Smith, published in 1750, and reproduces the engravings that represent the skeleton of this case. Reference is made to Mr. Sympton's paper on the subject, to the case described by Mr. Cesar Hawkins, to the specimen in the Hunterian Museum, and to some recently recorded cases, which, however, lack the post-mortem evidence that renders Dr. Lendon's essay so important to the pathologist.

RELIGIO MEDICI.

THE Union League Club resolutions on the death of Dr. Agnew, prepared by Chauncey M. Depew and presented by Sigourney W. Fay, contain the following: "If all Christians were like Dr. Agnew all men would become Christians. With him religion was not a cloak, but a career. It was not a formula, but a faith. It was not alone a liturgy or a creed, but the practice during every working hour of the commandment, 'Thou shalt love thy neighbor as thyself.' The profession was not only enriched by his genius and science, but thousands of young men owe to him the opportunities and examples which will enable them to take up his work and follow in his steps. The loss of such a man in the prime of life and usefulness is a public calamity, only mitigated by his good works while living and his glorious memory after death."

ALBUMINURIA IN THE APPARENTLY HEALTHY.

THIS subject was recently discussed in a short paper at the Islington Medical Society, by Mr. F. H. Stokes, as reported in the *Lancet*, March 10, 1888. He related a case in which a patient of his had been found, four years since, to have albuminuria by a consultant, who immediately took a very gloomy view of his case, and informed his wife that he would not live more than three months—a prognosis refuted by the gentleman continuing in good health to the present time, in spite of the persistence of albuminuria. There are no casts in the urine, and no other renal symptom. The urine is lithiacal, but this fault is largely influenced by the habits of the patient, especially in the matter of beer, which he used to take freely. When the beer is discontinued the lithiasis abates, and with it the albuminuria. In a happy interval of this sort the patient's urine was found free of albumen, and he was accepted for life insurance. Mr. Stokes mentioned two or three cases in which albuminuria existed for a long time in his experience without apparent harm, notably one of a gentleman still living, about sixty, in whose urine, twenty years ago, he detected a considerable quantity of albumen, which still continues. This patient has been a great athlete, and has climbed every considerable mountain that can be climbed in Europe. He is now infirm with prostatic and cystitic troubles.

Mr. Keele related a case of acute nephritis, with

hamorrhage, partial suppression of urine, convulsions, anasarca, etc., which did not prove fatal, as expected. All the symptoms disappeared, but the albuminuria persists.

Dr. Glover gave some particulars of two cases of temporary albuminuria, one in a lady about sixty-five, with severe vomiting, distressing headache, full pulse, and hot skin. There was, for one day, about a fourth of albumen. It was found that the diet had been too free, especially with regard to eggs, five of which had been taken in one day. A little starvation and purgation sufficed to remove the albuminuria and all the symptoms. In another case, that of a little girl about six, with "cold-water" feeling down the back, followed by fever, sickness, and coughing, there was slight hæmaturia, with corresponding albuminuria. The albuminuria lasted only one day, and the other symptoms gradually abated with rest in bed and other treatment.

The disposition of the meeting was to believe, with Prof. Grainger Stewart, that the gravity of mere albuminuria had been overrated.

OBITUARY. DR. EDWARD GREELY LORING.

MR. EDITOR.—Immediately after the death of Dr. Edward G. Loring, the New York Ophthalmological Society called a special meeting and the report of the committee then appointed was read and accepted at the last regular meeting of the Society. At the request of the Society I send you a copy of this report, hoping that you will kindly publish it in your JOURNAL.

Very respectfully yours,

WM. S. DENNETT, Secretary.

Dr. Loring joined the New York Ophthalmological Society, January 13, 1869. He was elected the President of the Society January 12, 1874. He died suddenly in this city April 23, 1888. During the twenty years in which he was a member of this Society he was a constant attendant at its meetings, no one was more beloved than he for his many social qualities and in the scientific work of the Society his word was listened to with a respect accorded to but few. It is fitting that a brief sketch of his life should be entered upon our minutes.

Dr. Loring was born in Boston, September 28, 1837. He was a son of Justice Edward Greely Loring. For a short time a member of the class of 1861 at Harvard College; he went abroad and began the study of medicine in Italy. For three years he was enrolled as a student at Florence and Pisa, and at the University of the latter place he was a devoted student in anatomy of Professor Duranti. In 1862 he returned to America, and in 1864 graduated at the Harvard Medical School, winning the Boylston Prize Essay.

Upon receiving his degree in medicine, Dr. Loring devoted himself to the study of ophthalmology under the direction of Dr. Haskett Derby, of Boston. He was appointed Ophthalmic extern by Dr. H. W. Williams, at the City Hospital, and subsequently served for a short term at the Massachusetts Charitable Eye and Ear Infirmary. In 1865, he established himself in practice in Baltimore, remaining there but little over a year when he came to New York to become associated with the late Dr. C. R. Agnew. Four years later this partnership was dissolved, and until his death Dr. Loring has practiced medicine in New York city.

He was a surgeon of the Manhattan and Brooklyn Eye and Ear Hospitals and subsequently a consulting surgeon of the latter institution. He was in 1874 appointed an ophthalmic surgeon of the New York Eye and Ear Infirmary, and held a similar position at the latter Hospital until this partnership was dissolved. original in thought, scientific in method, bold in execution, Dr. Loring was a skillful surgeon, a thoroughly-trained physician; as an author he was conspicuously known both in this country and abroad for his original contributions to medical literature. In this brief memoir it would not be in place to discuss the value and extent of his literary work. His writings were upon nearly every subject embraced in the science of ophthalmology. His text-book of Ophthalmoscopy, the completion of the second volume of which occupied the last days of his life, will remain for all time his most lasting memorial.

Dr. Loring made the Refracting Ophthalmoscope a working instrument, to which nothing of any importance, except the tilting mirror, has been added since. By whatever name the latest manufacture is known, this instrument is still the Loring Ophthalmoscope, vastly better than all its predecessors.

In the discussions of this Society he was frank and straightforward in his action and speech, scholarly in his address; the type of a brilliant, honest and independent man.

A keen observer, unflinched by the traditions of the schools, his opinions based on sound anatomical and physiological knowledge, he was a hater of sham, a follower of truth for the truth's sake.

Correspondence.

OVARIOTOMY IN AGE.

LONDON, ENG., May 23, 1888.

MR. EDITOR.—In the JOURNAL of May 3d I find an interesting case of "Ovariectomy in a Patient Eighty-two Years and Four Months of Age," by Dr. Homans. This patient certainly appears to be the oldest who has ever recovered from ovariectomy. But I am surprised to find that the author, as well as Dr. Lorini, who has made some wide literary investigations at the behest of Drs. Homans and J. S. Billings, failed to find "any case recorded older than seventy-eight years of age." In the *Buffalo Medical and Surgical Journal* for September, 1866, and in the *American Journal of the Medical Sciences*, Vol. LIII, 1867, page 284, a record will be found of Dr. Miner's case of ovariectomy in a woman aged eighty-two. The tumor was multilocular, and weighed nineteen and a half pounds. The extremities of the pedicle-ligature were passed through the vaginal septum. The patient died fourteen days after the operation. Schröder operated successfully on a patient aged seventy-nine, and on another aged eighty. Miner's and Schröder's cases are noted both in the second edition of Olshausen's "Krankheiten der Frauen," and in my "Handbook of Gynecological Operations."

I remain, dear sir, yours truly,

ALBAN DORAN.

THE IMPORTATION OF LEPROSY.

MR. EDITOR.—It may be a matter of interest to your readers, in connection with your remarks upon "the importation of leprosy" in the last number of the JOURNAL, to learn that within two years I have been consulted by two former residents of the Hawaiian Islands in relation to cutaneous manifestations, which, they feared, might be the early symptoms of that disease. If their fears had been well founded, what should have been done by their medical adviser for the protection of the communities in which they live, which should not as well be required in a case of syphilis? The spread of the latter through non-venerable channels is of not uncommon occurrence amongst us, and the chief difference between the two diseases is that the latter is more or less under the control of treatment, while the other is scarcely at all so. Not until complete isolation is enforced by national governments over the whole earth simultaneously against syphilis and leprosy, will these great and kindred historic destroyers of mankind become exterminated.

JAMES C. WHITE, M.D.

TREATMENT OF FRACTURES OF THE CONDYLES OF THE HUMERUS. A CORRECTION.

BOSTON, May 28, 1888.

MR. EDITOR.—The remarks of Dr. David W. Cheever, as published in your issue of May 17, 1888, in the report of the Suffolk District Medical Society, are so entirely misleading that it seems improper to let them stand without correction.

That I ever practiced or taught that fractures of the external condyle of the humerus should be treated in a straight position, is an absurd mistake. What I taught and advocated was that fractures of the internal condyle were to be treated in the straight position, while fractures of the ex-

ternal condyle was best treated by maintaining the arm flexed at an acute angle, for which purpose any splint is a dangerous nuisance. It is enough to place the hand on the opposite nipple and maintain it there by adhesive plaster a sufficient time.

Dr. Cheever says that I became convinced that although it was philosophically correct, it was not practical in its results. I taught that it was philosophically wrong and therefore impractical. Had it been philosophically correct it must have been practically correct. To reason otherwise is folly.

The slurring remark that I had picked up the idea from some French author is silly. No author ever advanced such an idea. A most original and excellent article was published, with plates, in the earlier numbers of the *Annals of Surgery*, advocating the plan of treating fractures of the internal condyle of the humerus in the straight position, and those of the external condyle in the flexed position at nearly a

right angle. It was written by Oscar H. Allis, M.D., of Philadelphia, a renowned anatomist and surgeon. He may be a Frenchman, but if he is, he is an honor to his native country, and to that of his adoption.

It is curious to remark that many years ago the same argument brought forward by Dr. Cheever was used by Pèzerat in favor of treating fracture of the inner, *not* outer, condyle straight, but Malgaigne declared it nonsense because the flexors arising from the inner condyle were thus made tense. In truth, the muscles have little or nothing to do with the question. It is the opposition of bone against bone that does the business.

Dr. Gay's remarks in the same number of the *JOURNAL* are sounder. It is evident he remembers the case of the child treated without splints in the wards of the City Hospital, the result of which was satisfactory in every respect, as I have ever found it to be.

W. C. B. FIFIELD, M.D.

REPORTED MORTALITY FOR THE WEEK ENDING MAY 26, 1888.

Deaths reported 1,893: under five years of age 594; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 329, consumption 283, acute lung diseases 232, diarrheal diseases 70, scarlet fever 37, typhoid fever 22, whooping-cough 18, measles 16, malarial fever 13, cerebro-spinal meningitis 10, erysipelas 10, puerperal fever 10, small-pox seven. From typhoid fever, Philadelphia 13, New York three, Baltimore, Boston, New Orleans, Pittsburgh, Milwaukee and Lawrence one each. From whooping-cough, Charleston six, New York five, Philadelphia four, Baltimore, New Orleans and Gloucester one each. From measles, New York eight, Baltimore three, Philadelphia, Pittsburgh and Milwaukee one each. From malarial fever, New York five, New Orleans four, Philadelphia and Baltimore two each. From cerebro-spinal meningitis, New York three, Nashville two, Pittsburgh, Milwaukee, Worcester, Salem and Holyoke one each. From erysipelas, New York six, Philadelphia two, Nashville and Lawrence one each. From puerperal fever,

New York seven, Philadelphia, Milwaukee and Fall River one each. From small-pox, New York four, Philadelphia three.

In the 19 cities and larger towns of Massachusetts, with an estimated population of 374,035, the total death-rate for the week was 19.22 against 20.51 for the previous two weeks.

In the 28 greater towns of England and Wales with an estimated population of 9,398,278, for the week ending May 12th, the death-rate was 17.6. Deaths reported 3,174; infants under one year of age 738; whooping-cough, 109, scarlet fever 45, measles 40, diarrheal 32, fevers 23, diphtheria 26, measles (Sheffield three, Manchester, Preston and Leeds one each) six.

The death-rates ranged from 12.5 to Cardiff to 26.7 in Bolton; Birkenhead 18.3; Birmingham 15.7; Bradford 17.0; Hull 19.1; Leeds 19.5; Leicester 18.5; Liverpool 17.2; London 16.6; Manchester 21.9; Newcastle-on-Tyne 21.7; Nottingham 19.2; Sheffield 14.8.

In Edinburgh 21.3; Glasgow 24.4; Dublin 23.1.

The meteorological record for the week ending May 26, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. ¹			Rainfall.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 2, 1888.

CRAIG, F. C., passed assistant surgeon. Detached from Naval Hospital at Norfolk and to the Naval Hospital at New York.

WESTWORTH, A. R., assistant surgeon. Detached from the United States Steamship "Galena," and to the Naval Hospital at Norfolk.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE FOUR WEEKS ENDING JUNE 2, 1888.

WYMAN, WALTER, surgeon. Leave of absence extended fourteen days. May 22, 1888.

MAORIDER, G. M., assistant surgeon. Relieved from duty at Marine Hospital, Chicago, Illinois, detailed as medical officer Revenue Bark "Chase," during summer cruise. May 19, 1888.

DEVAN, S. C., passed assistant surgeon. Granted leave of absence for ten days. May 29, 1888.

CARRINGTON, P. M., passed assistant surgeon. Granted leave of absence for five days. May 29, 1888.

SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at Huntington Hall, Massachusetts Institute of Technology, Tuesday, June 12, 1888, at 7.45 o'clock. Business: Dr. Thomas Dwight, "Demonstration of Models of Frozen Sections of Anatomy." Dr. T. M. Rotch, "Exhibition of Aseptic Appliances for Infant-Feeding." Dr. S. G. Webber, "Cases of Tumor of the Brain." Drs. C. F. Folsom, J. J. Putnam, W. N. Litchard and others will take part in the discussion. Dr. E. W. Cushing, "Studies in Malignant Disease of the Body of the Uterus, with Stereoscopic Views." Dr. George M. Garland, "Upon the Use of Goldsmith's Semperivivens." Members of the profession are cordially invited to attend.

ALBERT N. BLOGETT, M.D., Secretary.

A. L. MASON, M.D., Chairman.

RHODE ISLAND MEDICAL SOCIETY.—The Seventy-Seventh annual meeting will be held in Lyceum Hall, 62 Westminster Street, Providence, at 10 o'clock, A. M., on Thursday, June 14, 1888. The Annual Address will be delivered by Charles V. Chapin, M.D. Subject: "The Nature and Prevention of Scarlet Fever." The Annual Dinner will be served in Blackstone Hall, Washington Street, corner Snow. Dr. William H. Palmer, Anniversary Chairman.

W. K. WHITE, Recording Secretary.

H. G. MILLER, President.

NEW HAMPSHIRE MEDICAL SOCIETY.—The Ninety-eighth annual meeting will occur in the Hall of the G. A. R., 15 Warren Street, Concord, N. H., Tuesday, June 19, 1888, at 11 o'clock, A. M. The annual dinner will be served Tuesday, at the Eagle Hotel, at 1 P. M. Tickets will be for sale by the Committee of Arrangements at the opening of the morning session. The Anniversary Chairman, Dr. George Cook, of Concord, will preside. The Society will meet at 8 o'clock A. M., Wednesday, June 20, 1888, and any papers or discussions laid over from the programme of Tuesday will be in order.

APPOINTMENTS. NEW YORK POST-GRADUATE MEDICAL SCHOOL AND HOSPITAL.

At the meeting of the Board of Trustees of the New York Post-Graduate Medical School, held on Monday, May 28, 1888, the following appointments were made in the Faculty: Abraham Jacoby, M.D., Professor of Diseases of Children; Robert C. Weir, M.D., Professor of Clinical Surgery; Peter A. Callan, M.D., Professor of Diseases of the Eye; L. Bolton Bangs, M.D., Professor of Diseases of the Genito-Urinary Organs and of Venereal Diseases; Joseph E. Winters, M.D., Professor of Diseases of Children; O. B. Douglass, M.D., Professor of Diseases of the Nose and Throat. Dr. William A. Hammond being about to remove from New York to Washington, has resigned his position as Professor of Mental and Nervous Diseases. Dr. Hammond was one of the founders of the School.

BOOKS AND PAMPHLETS RECEIVED.

- Report of the Mitchell Library, Glasgow. 1887.
On Exercise for Prevention and Cure of Deformities. By A. H. P. Leuf, M.D., Philadelphia. Reprint. 1888.
Infantile Feeding, especially with Reference to Subjects with Infantile Eczema. By L. Duncan Buckley, A.M., M.D., Physician to the New York Skin and Cancer Hospital, etc. Reprint. 1887.
An Aseptic Atmosphere; Club-Foot; A Rectal Obturator; Palatoplasty. By David Prince, M.D., Jacksonville, Ill. 1888.
Atlas of Venereal and Skin Diseases; Fasciculus IV. By Prince A. Morrow, M.D. New York: Wm. Wood & Co., 1888.
Inebriety; its Etiology, Pathology, Treatment, and Jurisprudence. By Norman Kerr, M.D., F.L.S., etc. Philadelphia: P. Blakiston, Son & Co., 1888.
The Physician's Leisure Library, No. 7; issued monthly. The Modern Treatment of Pleurisy and Pneumonia. By G. M. Garland, M.D. Detroit: Geo. S. Davis, 1887.

Guide to Health Resorts in Australia, Tasmania and New Zealand. Edited and compiled by Ludwig Brock, author of the Australasian Medical Directory and Handbook. Centennial edition. Published at the Australian Medical Gazette Office, Sydney, 1888.
Dissolution and Evolution and the Science of Medicine. An Attempt to Co-ordinate the Necessary Facts of Pathology and to establish the First Principles of Treatment. By C. Pitfield Mitchell, Member of the Medical College of Surgeons, England. London: Longman, Green & Co., 1888.
An Address on the Treatment of the Gouty Constitution. By I. Burney Yeo, M.D., F.R.C.P., Professor of Clinical Therapeutics in King's College, London; and Physician to King's College-Hospital. Reprint. 1888.
The Physiological Argument in Obstetric Studies and Practice. By A. F. A. King, A.M., M.D., Washington, D. C. Reprint. 1888.

Address.

RE-ESTABLISHMENT OF THE MEDICAL PROFESSION.¹

BY R. JOY JEFFRIES, A.M., M.D., OF BOSTON.

MR. PRESIDENT and Fellows of the Massachusetts Medical Society: It is very generally agreed that the lawyer, the minister, the squire, and the physician do not hold the same relation to the community as they formerly did. As that position was one of trust and confidence, it well behooves us to carefully study the causes that have broken it down, and correct, if possible, any fault lying at our door. On the other hand, it is equally our duty to right ourselves before the community, if our efforts have again placed us in a position to be trusted and confided in. Moreover, if the community misjudge the whole from a part of the profession, it is the duty of those truthfully striving not to have their labors misjudged and injured by any false sentiment towards others not so acting.

There are, of course, many natural causes for the three professions not holding their ancient position. They are now but three of many existing in the world. Science and art and technology have introduced distinctly professional fields of study and occupation.

In the older compact and more isolated communities the diffusion of knowledge was less. The three professions represented nearly the whole of it. Moreover, the diffusion of falsehood was less, though credulity remained. All forms of medical chicanery have increased and widened with the means of reaching by the public press and the post office a larger circle of the ignorant and credulous, poor and rich. Wealth does not now, as formerly, include knowledge and common-sense. Money is more easily gathered than knowledge, and its accumulation does not preclude the continuance of its owner's previous credulity or gullibility. Moreover, money renders its sudden possessor more dogmatic in his superstition and infallibility. The poor man is open to teaching and advice, the rich man thinks that his wealth places him above both of these.

In the village life of former days, any question of medicine, natural science, or natural philosophy was referred to the physician, and his decision taken. The common-sense imbibed in medical education and practice enabled him to expose the falsehood started by cupidity and kept alive by credulity. The same confidence was reposed in the minister as to all matters of morality or theology, and in the lawyer as to property and legislation. But we are not concerned with them. Our own position alone should occupy our thoughts and efforts.

Why have the profession as a whole lost their hold on the community and the respect naturally theirs? In this country democracy has brushed away any glamor of office, all that which hedges in a class or an organization. Even that which clings longest, namely, any peculiarity of manner or dress which separated us from others, has melted away before the sun of common-sense and general intelligence. When the physician possessed more knowledge, more education, than those about him in his community, he was respected for these as he should have been. But now-a-days those about him have in the general advance

of education gained upon, and only too often outstripped him. In the struggle for existence, the doctor goes to the level that he is entitled to by his education and the refinement this gives him. If the ranks are filled with men without education, except that which they are supposed to have medically, then the laity, finding that such are destitute of the former, very fairly doubt the existence of the latter. Good breeding and a good education are not now, as formerly, the natural attributes of those legalized by a diploma. Cheap and charity medical schools have multiplied over our country to a greater extent even than seminaries, colleges, and so-called universities. The profession well know that these medical schools are but local advertisements, and that in their struggle for existence they underbid each other, not only as to medical education, but also receive as students and give medical degrees to men comparatively destitute of even a common education. The various State legislatures grant these medical schools the power to issue such degrees, which the laity ignorantly accept as a proof of education, and that is what they are sold and bought for.

Now, in course of time the laity have found out that the holding of a medical degree, being a doctor, does not preclude ill-breeding and lack of education. And they have naturally arrived at the conclusion that a medical man may be pretty low in the social scale gauged by education; hence that the study and practice of medicine mean but little.

To give every individual in the community, without respect to color or sex, an opportunity for the best education he can attain to and his ability deserves, is a noble charity on the part of the State or the private citizen. For the public or private institution to sanction by its seal ignorance and quackery in any form, is simply cheating the community for the moneyed benefit of the few and unworthy. The poor and unlearned are deluded by the title of doctor, and the delusion has the sanction of the State by the judge on the bench deciding that one medical degree is as good legally as another. The laity know nothing of and cannot judge medical matters, and hence are easily duped in giving State sanction to any and every form of rascality under the guise of medical teaching, from a Druid college to a Christian scientist's bucket-shop, thus helping to fill our graveyards and insane asylums. The community demands protection in everything except precisely where it needs it; namely, from ignorance, prejudice, and superstition.

It is from such causes, it seems to me, that the medical profession as a whole has dropped in the social and educational scale, lost power and lost influence. The public recognize that it is largely entered into as a trade or business, and that many of its members hold degrees and diplomas purchased of the mills, legalized it is true. But so are the dramshop and saloon legalized. The professors in our law schools well impress on their students that law has nothing to do with justice. One doctor is the same as another to the public, to such an extent that even men of attainment and culture fail to distinguish the honorable and well-educated physician from the quack and the charlatan.

I have found many truly scientific men treating us most unfairly in this respect. They tolerate licensed or unlicensed pretenders in medicine without separating them from those of the profession whose knowledge and proved ability really place them on an equality

¹ The annual address to the Massachusetts Medical Society, June 13, 1888.

with themselves. They give credence to and put faith in, associate with, men whose ignorance, charlatanism and want of breeding are such as they never would admit them in their own field of study. Men of science in other branches receive from no class greater recognition and respect than from the best men in our profession, who know enough to appreciate knowledge and its attainment. It is but fair that we ask of them such discrimination as they employ towards each other, and not attribute any protest on our part to narrowness, professional jealousy, etc. It can only be that they as members of the laity imbibe prejudice from inability to discern and judge of medical matters.

The teachers and the examiners in the best Medical Schools all over the world are demanding greater educational requirements of men desiring to study medicine. And this most rightly, because it is impossible to teach medicine to those without thorough foundation. They cannot learn, and to give them diplomas half-earned, but adds to the load the educated portion of the profession have to carry. The refinement which education gives is needed in the practice of medicine. Education of a high standard is needed for the doctor to hold his proper relations to the community, besides a thorough knowledge in his calling.

Medicine can only recover its former just position when the world is forced by its existence to recognize that to be a graduate of a good medical school means to have the education of our best universities in addition. The world will not now believe and trust in a man's medical knowledge unless they have proof of other education besides, which adds force and power and refinement. The doctor must be, can be, and will be, a man of science. As such we can ally ourselves with the great body of men striving for knowledge and seeking truth. From the lack of this, a large part of our profession is not distinguishable from the man of business or the tradesman, perhaps perfectly respectable, but perfectly commonplace, and worthy only of the position trade and business take in the community.

The avenues to wealth or official power are quite outside our calling. As physicians we cannot compete with trade or business. But this is our common lot with other scientific men. Wealth is a mighty power but it falls palsied before knowledge. Slowly but surely, I believe, is the former yielding place and respect to the latter. Certainly Cræsus is never more flattered than when treated as possessing knowledge, education and the refinement it brings.

Are we not in honor bound to do all in our power to bring up the standard of education and the standard of professional requirements in our callings? Educators tell us that it would be a good thing for the world if nine-tenths of our so-called academics and little colleges were swept away and merged in large and strong institutions. Certainly it would be a good thing for the world and for our profession if nine-tenths of the medical colleges were swept away and what was good in them gathered into a few great medical universities, placed where teaching and study could best be carried out.

Why should not this Society quickly raise its standard of requirement for admittance, such as would render membership a proof of educational refinement and professional knowledge? I grant you that moral

courage and backbone are needed to do this. But I insist that the possessors of these exist among us, and await only support from the majority. Let them have it, and this at once, or else the best men in the profession must separate and form themselves into a body known and respected for possessing what the others do not. May this necessity never come in my day. But we must sympathize with the man of scientific attainment and educational refinement forced to recognize another who is ill-bred and half educated, simply because the latter holds also a medical degree which insures nothing of these. That is trades union.

I hear expediency, desire to conciliate for ultimate purposes, compromise, saying, perhaps with bated breath, we cannot be so high-toned, we cannot expect doctors to have the refinement of education, or more professional knowledge than enough to get along in practice. I answer at once, with no hesitation or reservation, that there is an increasing number of men in our ranks who have educational refinement and high professional attainments.

Again, I hear it said that the requirements of a physician's vocation tend to break down his literary life and hinder any advance in his medical study. This is but an attempted defence of the ignorant who never should have been allowed to enter our ranks, and who have done so for trade through chicanery. No one of the laity has to descend to the low offices the sacred duty of a physician calls upon him to perform for his patient. Such never detract from his refinement or his dignity. Circumstances may call upon us at times to do any manual or menial work. We elevate it, not degrade ourselves, by performing it as a part of the burden we assume with our title. There is nothing demeaning in taking care of your horse, your furnace or your boots; there is in saying "I be," and in calling yourself an "allopath."

A knowledge of the formation and working of the human frame, so-called anatomy and physiology, the recognition of the diseases incident to humanity, the control of these latter by hygienic methods, drugs or surgical interference, are what separate our profession from the rest of the community. We are a very distinct class, wholly apart from the rest of our fellow-men who have gained or who are pursuing knowledge. Any intelligent person in proportion to his intelligence or capacity, may have some ideas of justice or injustice which we call law, of right or wrong which we call morality or theology, or of the great principles of the other professions now recognized. But no man or woman, no matter how intelligent, can make any truthful decision as to our bodies in health or disease, or how the latter may be prevented or mitigated by any human means. It is only the very shrewd among the laity who recognize and act on this. I do not mean the blind trust of the ignorant and credulous or superstitions.

The great mass of the laity feel perfectly competent to judge of medical matters as they do of other things, where there is seeming cause and effect. They feel as if it was an insult to their common-sense and discernment, not to be able to instantly judge, where we with all our knowledge and experience, feel still incompetent to decide the present or the future. They regard the cautious safety in which we feel our way, as only a proof of ignorance or incapacity, referring to the glib answer they get from the charlatan in support of their opinion. Nothing irritates men or

women of the laity more than to have their medical judgment shown up to them as silly credulities. They stand by these, and the quack who has induced them, the firmer, the more they have been deceived. The greater the knowledge and education or even the scientific attainments, the more firmly will the laity feel assured of their capacity of judging things medical, and resent exposure of their special fad. In their own department of learning or research they would derisively laugh at any one arguing from such evidence as they have accepted without challenge in matters medical.

I have often shown a business man to what silly credulity he has yielded in what concerned his own life and health, or that of those he loved best. And I have asked him what would be his position if he yielded to such charlatanism in his business and everyday life, acted on such evidence, and adhered to such falsehood. Many such a man has afterwards thanked me for the new thoughts I had given him, and the warnings to balance evidence with common-sense and applied intelligence.

Human nature is such that you often cannot argue with or convince it. But human nature is very sensitive to being proved silly, or even credulous. Nothing is more powerful than the exciting a smile at an opponent's expense. Now when physicians meet in social intercourse with each other, what for them is more entertaining or affords greater amusement, than the relation of their individual personal daily experience of the laity's medical ignorance and hence medical credulity? No matter how great the rascality of the special quack or charlatan in question, he will not be inveighed against, the laugh is always at the expense of the dupe, the greater whose intelligence, the greater his silliness of action. There is no more complete satire on humanity than just this never-ceasing fund of entertainment the laity of all classes afford us. Could the public hear and understand our collected knowledge of this folly, their ears would tingle, and if shrewd enough, they might profit by it. But the tailless fox, even with an unhealed stump, will recommend the trap to his friends. None know this better than the quacks and charlatans. The laughter we enjoy at the laity's expense is a bitter medicine for them, but when judiciously administered may often be of great benefit. Its exhibition requires tact and moral courage. The "paths" who fatten on the laity's medical credulity, never offend the laity's belief in the infallibility of its judgment, for this would soon affect their pockets. The "paths" pretend to be doctors; the pretence satisfies the laity.

Our profession know only too well that there is no limit to human gullibility in all matters medical. High and low, rich and poor, ignorant and learned alike, are human in all that relates to their bodies, and hence gullible, credulous and superstitious. Now it requires very little brain-power to fool those who know nothing of the subject concerning which they are being fooled, and who are *willing* dupes. The ignorant laity will swallow anything mentally and physically, and so will the intelligent and the learned, if you only favor their conceit of knowing more of our profession than we do ourselves. This is the secret of the various pathicquack's success.

The community never challenges the charlatan's knowledge or ability whilst accepting his statements. To be a quack doctor is the easiest thing in the

world; requires but little sharpness. The most successful medical pretenders could not earn their salt in any business pursued by their clients.

All this proves that the whole laity are but a parcel of children in their relation to us, destitute of discernment, ability to discriminate, power of observation and deduction. A man or woman in bodily pain or fear, or seeing those they love so, is wholly without mental balance and seems to lack at times even common-sense. Very little sharpness is then needed to prey upon human weakness. The subsequent shame of having been preyed upon when the quack is exposed, but renders the latter's dupe his strongest defender. The laity always have resented and always will furiously resent being considered what the intelligent and educated physician knows they are, from that knowledge which he has and they have not.

Shall we simply avail ourselves for gain of the laity's ignorance of the subjects we are familiar with, their passions, prejudices, superstitions and unfathomable credulity? Is it not dishonest to do so, what in business is called sharpness? We may have to bow before our patient's knowledge or scientific standing, but real or unreal pain or fear will readily make him bend the knee to our true or supposed superior position. Shall we take advantage of his condition? Why not, says the doctor whose profession is a trade; why not, says the sharp business man, it is perfectly legal. But law is not honor or justice. It is *our* duty, a part of the work of *our* life, to protect the community, to resist quackery, by always and at all times unmasking it, firmly, fearlessly, earnestly.

Men and women are attracted to this or that quack by the special "pathy" he pretends, and in belief that the quack applies the special pathy to his or her case. A man goes to a gambling hell in the belief that he is to play at a game of chance, and will excuse himself on this. The societies who are fighting these dens show up their methods, and prove to their patrons that it is not a game of *chance*, but a game of *cheat*, — not the accidental turning of a card or rolling of a ball, but that these are turned or rolled by the gambler to fleece his victim. Now why not be perfectly straightforward and honest, and have moral courage enough to plainly tell the community the truth, namely, that there is no such thing as a "pathy," that there is no true homeopath, that men merely call themselves that or other things simply for gain? If you, as can so readily be done, show your client that the quack to whom he is attracted by any special pretence does not even practice *that*, you will help save him and the community from fraud.

We know that this is perfectly true, and we are in a position to know whilst the laity are not. Do we not fail in our duty in letting them be deceived? Does not our silence and hence seeming acquiescence arise from motives which will not always bear the light? I am afraid that our so-called desire not to make martyrs of them does not always arise from simple prudence. Is it not rather a shrinking from offending our patrons and wounding their self-conceit and their misjudgment of things medical? We know all about the quack and pretender, licensed or unlicensed, and we simply assist his cheating the community, become *particeps criminis*, by in any way *seeming* even to recognize him professionally or socially.

One has heard in the past a great deal about physicians by their exposing and opposing quacks only

inducing the laity to protect and patronize them as injured beings. Time has wholly convinced me that the laity only regard our tolerance and forbearance as proofs of our ignorance and wrong position, and whenever, as is not infrequently the case, they learn of the true condition of affairs, simply despise us for want of courage and ability to hold our own. Professional intercourse with quacks of any kind is foolish, and is sure to react upon the one who attempts it, whatever his motives. Indeed such professional or social intercourse is worse than folly. It is of no use to beat about the bush. We know perfectly well that these men, no matter what their so-called standing in the community or number of dupes as patients, are cheating those confiding in them, not even following their pathy, as their clients believe, but simply doing what will draw from the pockets of the latter. How can you socially or professionally recognize such men and women without helping them defraud the laity, whilst you finally but receive the latter's contempt as your reward.

Next to honesty, moral courage pays best in this world in the long run. I am sore afraid that the community loses and the quack gains by the lack of it in our profession, where, if anywhere, it ought to be found, and where most certain final failure follows its absence. I mean true moral courage, and not an assumed bluntness or brass too often found in imitation of it. Shrinking from one's duty in exposing pretence to defend our patients and their surroundings from elicaucery, is timidly called necessary expediency. The charlatan laughs at us for it, and the laity, when they sooner or later find it out, join in the laugh.

We do no good in demeaning our profession. Even if our motives were good in semi-recognition professionally or socially of quack pathies, the community would not give us the credit of such motives. When a quack's dupe has unearthed the rascality, his reaction is pretty violent; and if the physician, by action or inaction, has seemingly helped the rascality, he will come in for his share of the blame and be heartily despised.

I have heard it argued in the past that the various pathies in medicine, which follow one another in turn, have from the ignorance of the laity gained such a hold that it is better policy to compromise with them, and seemingly recognize them, although they are pursued simply and solely because they are an easy means of getting money from dupes. Moreover, that these dupes are often the highest and most talented in the land, hence those who cheat them must be respected by us. Why not respect the gambler and unco-steerer, because his dupes are often the highest and supposed best in the land? No, our study of medicine teaches us the truth, which the laity cannot understand without the same study. To deny or act contrary to this truth is a falsehood, whether you call it expediency, compromise, or a pharisaical desire to live at peace with all.

One of the worst features and most dangerous tendencies of this very community is the desire to compromise, which is generally the combining the wrong of both sides, each party giving up what it knows is right and true. I have often received friendly hints and chides for uncompromising opposition to medical quackery in the licensed and unlicensed. I can now look back with pleasure to not having yielded to these, but followed my own instincts and belief in my posi-

tion of hatred for and determined fighting against every pretender, and in never hesitating to express to his dupes the exact truth, whether pleasant or unpleasant for me or them. I have lived to see, my enthusiasm if you will, honesty and fidelity to the profession surely, recognized by and respect wrung from these very pretenders themselves, as proved by their sending their clients to me.

Certainly honesty is the best policy, however low that is as a reason for right action. If we make quacks respect us, the community certainly will also, and we shall thus raise our profession to where it belongs before the world.

I am sorry to see a desire and willingness to meet quacks and argue about quackery, as if this was absence of supposed professional jealousy, and showed a broader and more catholic spirit. Do the physicians who would do this know how the quacks laugh at them and despise them for it? A quack doctor knows he is such, and counts you a fool if you don't know and can't detect it, but he will be sharp enough to take advantage in any recognition of him as helping him dupe his victims. He laughs at and uses you whilst you help him cheat the community. Touching pitch defileth the fingers, and, if the pitch is hot, burns them also. Stop all social, as well as professional, intercourse with every pretender, and you will get his and the world's respect.

Our social position is a delicate one to touch on, as are all social questions in public, but our relations to the family and the individual are peculiar and often very close. Whilst in the community at large a person gravitates to his social level, it should not and cannot be so with us physicians. Our professional calling should render us the social equal of any. Where rank and caste prevailed, the physician started with but little tolerated social position. As the profession has risen in scientific attainment, it has gradually claimed and received social recognition for itself, through itself. It has to contend with all powerful rank and title and office. It speaks well for our calling that it has wrung even toleration from them. But this it has done only by showing superiority in scientific attainment, hard work in seeking and accumulating knowledge, which is power.

In our country the social lines are as strongly drawn as where rank and caste prevail, but we do not have these latter to contend with in taking or maintaining our social status. What position we occupy depends upon ourselves. In this a physician establishes his own status. The force of position and family, inherited from former times, has been since our Civil War pretty thoroughly broken down. Our communities are in a transition stage. What formerly existed can never prevail again among us. Social force and power always have been and will be influenced by wealth, which now seems to govern above its legitimate authority. Of course, social refinement and cultivation must greatly depend on accumulated wealth in the community, and if the latter is used to promote the former, then civilization is advancing among us.

Already, however, the accumulation of money has reached its limit of effect and power. One Crcesus is very much like another. Midas, whilst at first he is most lavish to obtain social recognition, soon becomes more eager to help his descendants to a cultivation wholly dependent on knowledge and its pursuit.

If now the cultivation and refinement which family gives, is to be brushed away by democracy, and if democracy is not to bow down to accumulated wealth, then where shall social power and recognition come from? What shall constitute it? To me it is very plain that it can only come from and really exist in those who become refined by learning, the pursuit of knowledge, and the search of truth for truth's sake. Cultivation makes refinement. An uncultivated community cannot be a refined one in our country. I think I see the signs of culture becoming a social force, of a society based on the power of knowledge and the amenities of life this brings with it.

In such society our profession should be, and duly recognized there. Can we as a body claim such social recognition? Where are we to-day in the science and literature of our country as a body? When social distinction depends on the successful pursuit and accumulation of knowledge, and the character and refinement this gives, where shall the physician be placed? Is it not plain that he must gravitate socially to the level his ignorance drags him? Is it not plain that the lack of educational refinement holds the profession from the social position it would naturally have? Has not the profession lost its force in the community from lack of the power of knowledge? Is not even now the individual physician's social position dependent on his individual educational refinement?

The community is forced to grant us a knowledge of things affecting the public health. Hygienic medicine is perhaps more respected than any other branch. Those pursuing it have gained their position by proving their knowledge. In time of panic we are always looked up to for advice, freely given by us, but rarely followed if it affects the individual pocket or the pockets of a class. Against human greed we are comparatively powerless. When to this greed is added lack of every moral restraint up to absolute criminality, then we can hope for but little good effect from our efforts. Should we not for that very reason more strongly put them forth.

A CASE OF NEPHRORRAPHY FOR MOVABLE KIDNEY; COMPLETE RELIEF OF SYMPTOMS. REMARKS UPON THE SUBJECT OF MOVABLE KIDNEY.¹

BY MAURICE H. RICHARDSON, M.D.

Surgeon to the Massachusetts General Hospital; Assistant Professor of Anatomy, Harvard Medical School.

A GREAT deal of attention has been paid to this subject during the last ten years. Before 1878 much had been written, but little had been done to relieve the symptoms caused by movable kidney beyond the adjustment of various pads and appliances to keep the organ in its proper position.

Dr. Grenville Dowell² in 1879 published a case in which he passed a seton through a movable tumor of kidney and out of abdominal wall. There was some hæmaturia. The seton remained in place three

months, and gave some relief. At the end of that time the tape broke and came away. The seton caused persistent and offensive discharge. Later Dowell introduced the seton again without giving as great relief as before. The patient finally went crazy and was taken to an asylum. Dr. Smyth removed the kidney, which was found to have a scar two and a half inches long upon it from the cutting out of the seton. The patient recovered.

In 1881, Hahn³ published his method of fixing a movable kidney by lumbar incision. Of this operation the *London Medical Record* said (1882, p. 57):

"Considering that the extirpation of the kidney is an exceedingly serious operation, and that, moreover, by the removal of one kidney an increased function is thrown on the other possibly defective kidney, the surgeon will welcome the new method recommended by Hahn. He has operated twice already, completely relieving the patient in one case, and greatly alleviating the other.

"Patient is put on the left side. Long cut from the ribs to the pelvis on the outer border of the *erector spinae*. Catgut sutures, etc. He says that in both cases the kidney became movable again after a time, and he recommended that the fatty capsule be opened and separated from the kidney, and stitched to the wound, and the kidney fixed low down."

Since the publication of this article, the operation of fixation, called by Hahn "nephrorraphy," has been done a considerable number of times by various surgeons. Some are opposed to this operation because it is not, as yet, sufficiently tested, and prefer the more dangerous operation of nephrectomy, but it seems more conservative to follow the opinion expressed by Wagner in his review of an article by Linder in the *Centralblatt für Chirurgie* for 1888, that "while it will take years to estimate the value of this operation, yet on the other hand a series of very good and lasting results have been gained by the harmless nephrorraphy so that we can never agree to extirpation of a healthy movable kidney till nephrorraphy has been tried."

In 1879, Keppler⁴ called attention to the fact that movable kidney without any other complication (such as twisting on its axis, etc.) can have great effect on ability to work, can disturb the functions of the organism, and give cause to constantly developing disturbances of nutrition, so that on this account simply an operation is justifiable. He reported eleven cases, all of the right kidney, five men and six women, in whom the symptoms were digestive disturbances, chronic constipation, neuralgia, etc., and upon two of whom Martin performed nephrectomy, with complete recovery. Previous to this time this condition of the kidney was treated entirely by appliances to keep it in position. The first of these two cases of nephrectomy was in a woman forty-nine years of age, who had had the symptoms eight years. The kidney was removed by incision in the *linea alba*. She made a good recovery without fever. The second case was a patient thirty years of age. Recovery as before, with only slight rise of temperature. Dr. Carl Lauerstein⁵ reported a successful case (since dead) of removal of a healthy movable kidney by Martin.

Four later cases reported by Martin.⁶ The first

died from inanition, the second from sepsis, the third in six weeks from chronic peritonitis, and the fourth made a complete recovery.

The number of operations in this line has diminished of late years, thanks to Landau, who showed in his monograph that a movable kidney was not in itself dangerous to life, and that there was no case cited in literature of death due to movable kidney. Especially have Billroth and Czerny upheld the position that the indication of nephrectomy on movable kidney should be limited as much as possible, and that it will be the work of the future to fix the offending movable kidney by surgical means, and not to destroy an organ whose function is normal.⁷

Gross has collected seventeen cases of nephrorraphy, with death in one case, relapse in four, and partial success in three. Performed by Köster, Esmarch, Launcestein, Schede, Kümmell, and others. In most cases the trouble was lessened or disappeared entirely. Brodeur gives the following figures of kidney operations: 327 operations, 212 women, 94 men, 15 children, and 6 not given. Of these, 255 were nephrectomies, 125 by lumbar incision, with 78 recoveries 62 1-10 %, 110 by abdominal incision, 55 recoveries, 50 %. 43 nephrotomies, 34 by lumbar incision, 23 recoveries, 67 6-10 %, 9 by abdominal incision, 7 recoveries, 77 %.⁸ (Gross, 1885, 93 cases, 71 recoveries.)

10 nephrorraphies, all lumbar, with one death. (Gross 17 cases, one death.)⁹

The treatment recommended for movable kidney by different surgeons ranges from operations of considerable severity where the mortality is high, as above, to the application of contrivances for holding the kidney in place. In selecting the operation suitable for a given case, we must first carefully consider the symptoms present, the possible danger to life if they are left unrelieved, and how far we are justified in subjecting the patient to the risk of a dangerous operation to relieve symptoms of pain and discomfort.

It is certainly very seldom that a movable kidney endangers life; some writers deny that this condition is ever a dangerous one. A very large number of cases of movable kidney have been recorded by various writers up to the present time. A great many different causes are given for this condition of the kidney. Prominent among these causes is the absorption of the perinephritic fat. Yet it is as common for men to lose fat as for women, while they suffer much less from the affection. Many claim that women who have borne children are especially liable to dislocation of the kidney, but Linder,⁵ on the contrary, has observed a number of his cases in nulliparae, where there could be no question of any laxity of the abdominal wall. He considers the condition a congenital one.

Landau⁹ in his monograph on wandering kidney, gives as the most important and prominent cause the disappearance of fat from the fat-capsule, looseness of peritoneum, where the fat which has been present in large quantity is suddenly used up, as it is in severe, acute affections. An important rôle in women is played by laxity of abdominal wall, especially its frequent consequence, a pendulous belly. The intestines exert a dragging influence. He shows that affections of the genital organs cause movable kidney, as by causing hydro-nephrosis; also, it may be caused by pressure of the pregnant uterus on the ureter, by

tumors, etc. Other causes are trauma, constant and severe coughing, labor, lifting of heavy burdens, straining at stool. All these exert a loosening influence upon the capsule. He can find no cause for movable kidney in corsets or lacing. Cause of the mobility of right kidney rather than the left is due to unequal means of fastening the two kidneys. In 178 cases 151 were right, 13 left and 14 double.¹⁰

Ellinger¹¹ shows that in many women who have been treated gynecologically in vain, the cause of their trouble lay in a movable kidney, and cites four cases of his own where this was so. He did not consider this a sufficient cause to demand extirpation, in spite of many favorable experiences of Martin with nephrectomy, and held that a bandage is indicated. Landau cites 314 cases, 273 women and 41 men. A great many symptoms are described resulting from movable kidney. Landau speaks of laceration and compression of nerve-roots, bloodvessels, and functional disturbances; he considers symptoms of the strangulation of the kidney important, and finds the cause of local disturbances due to interference of local circulation in the movable kidney, caused by torsion of the kidney vessels as shown by experiments on animals.

Stiller, in a synopsis of a paper by Dr. Muller,¹² quotes "Many cases of dilatation of the stomach and of dyspepsia, were observed in connection with movable right kidney, which was evidently the cause of them, as no other could be found. The cases were observed mostly in young girls who laced tightly and performed severe work."

Bartels gives the following explanation: "The kidney is pushed forward and upwards, pressing on the pars descendens duodeni, which cannot move owing to lack of mesentery, consequently easy emptying of the stomach is hindered, the muscular layer is strained and finally becomes lax. The stomach becomes dilated, and severe chronic gastritis is set up." The writer, from observations of two cases, thinks that the sphincter pylori must be dilated, and also that part of the duodenum between the stomach and the place where the kidney presses.

Linder¹³ speaks at length of the subjective symptoms of movable kidney, some of which are almost pathognomonic signs, (contrary to Landau). Vomiting, loss of appetite, *factor ex ore*, etc., and intestinal troubles, especially after constipation. *Factor ex ore*, the most diagnostic sign: "several cases diagnosed from this alone," yet no cause for odor given, unfortunately. The climax is reached when the writer asserts that the greatest part of stomach disturbances and a very great part of the habitual constipation of women of young and middle age, is due to mobility of the right kidney.¹⁴

Prognosis. In an uncomplicated case of movable kidney it is probably true that there is no danger to life. Linder denies, as does Landau, that any "direct, acute danger to life is imminent." Leaving out of consideration those cases of movable kidney where there is a hydro-nephrosis, or other conditions where the opinion is unanimous that either nephrectomy or nephrotomy is imperative, we are brought to the question of selecting in a given case that method of treatment which promises the greatest relief to the patient with

the least risk to life. Many authorities assert that in the most, if not all cases, nothing is necessary beyond a suitable pad, to make the life of the patient one of tolerable comfort. Linder recommends first a bandage. Landau maintains that in fresh cases, horizontal position long maintained, will effect a cure. He says it is impossible to restore a kidney to its original position and sew it there. He finds the best thing to do is to immobilize the kidney, and that this is best accomplished by the modern long corset, which covers the whole abdomen and supports it. Ellinger, after many unfavorable attempts, had a bandage made which fitted his case.

Niehans¹⁵ favors the bandage, and proposes one used in a case of his own, with immediate and beneficial effect. Various other writers report cases where the application of a bandage has been followed by complete relief from symptoms.

Hahn¹⁶ in his original article, reviews cases of nephrectomy for various causes and speaks of its dangers. It is justifiable only when the life and happiness of the patient are threatened and the disease can be removed in no other way. He then proposed a new operation "Die Operative Fixation der Beweglichen Niere." He had two patients, one probably with stone in well kidney, and in the other both kidneys were movable. Extirpation was not to be thought of. Lumbar incision along the sacro-lumbar muscles from the twelfth rib to the crest of ilium, etc. The kidney still in its fatty capsule was then drawn forcibly back into the wound and sewed to it by six or eight catgut sutures. Then the whole wound was stuffed with carbolic gauze. The first bandage was changed the fifteenth day, the wounds were closed in about four weeks, and the kidneys lay immovable and firm in the sewed condition, as immediately after the operation. In the first case, the troubles disappeared after the operation. In the second case, the troubles were diminished, but not entirely removed. Later, the kidneys became somewhat movable owing to standing up and moving about. The adhesion did not seem to be great enough to bear permanently the weight of the kidney when standing. It seems advisable in order to gain greater security, to open the fat capsule on the convex edge of the kidney, remove it from the posterior surface, and sew this loosened part into the wound. In this way a firmer adhesion would be secured. An indication to extirpation of a movable kidney, Hahn sees only when it is diseased, which of itself demands removal. Hahn performs this operation, which he considers perfectly harmless, only when great disturbance caused by the movable kidney cannot be gotten rid of by the ordinary means.¹⁷ He considers that the extirpation of a healthy kidney is justifiable in the present state of the question, only when fixation is without success.

In the discussion of Hahn's paper before the German Congress, Landau maintained that the sewing of the dislocated kidney is as ineffective as it is dangerous, as in this way the gland is not fixed in its normal condition. The vessels and ureter suffer from the faulty arrangement, and if pregnancy should take place, the latter might be easily compressed, and hydro-nephrosis might result in consequence. In double, especially congenital movable kidneys, no attempt at

operation should be made. If the dislocation were due to trauma one should give, beside the application of a bandage, a fat-forming diet.

Küster and Esmarch have each fixed a movable kidney once after Hahn's method. In both cases, the disturbances of the patient were diminished, but did not disappear entirely. A third report gave the same result.

SYNOPSIS OF OTHER CASES.

Bassini.¹⁸ Woman twenty-seven years of age, movable kidney right side, cause unknown. Hahn's operation, four stitches, wound healed ninth day, discharged on twentieth day; cessation of disturbance.

Robert F. Weir.¹⁹ Hahn's operation, patient crushed between two wagons six years before; since then had suffered disturbances of extraordinary severity; two months after the operation the patient had evidently recovered, and the pains had decidedly decreased.

Ceccherelli.²⁰ Woman twenty-eight, left movable kidney; severe disturbances for years; to make the kidney more secure, passed the stitches round the twelfth rib. In spite of perfect asepsis the patient died in forty-five hours after the operation. This is the only fatal case.

De Paoli.²¹ Woman thirty years of age; right sided lumbar pains with increasing digestive disturbances; bed position unendurable in any way. Standing was endurable. Walking soon followed by pain and vomiting. Abdomen pendulous; dilatation of stomach; movable kidney on right side, easily replaced but causes pain. Nephrothorax performed; twelfth rib cut through to gain room; kidney fixed with numerous stitches; discharged at the end of seven weeks cured completely of disturbances.

Agnew.²² Man, thirty-two years old. Seven years before while exerting himself greatly, sudden pain in right lumbar region; constant pain thereafter; right movable kidney. After many unsuccessful attempts to retain kidney in normal position by mechanical means operation decided on; lumbar cut. Kidney drawn into abdominal walls. Catgut sutures through capsule; drainage; antiseptic bandage; healing in six weeks; in one month return of movable kidney. Some months later kidney extirpated from lumbar region. Recovery in four weeks.

In the discussion of this case, Gross remarked that in 17 cases of sewing of the dislocated kidney in its original position one was fatal, three were only partially successful and four returned. In spite of this he would always recommend the less dangerous operation before deciding on extirpation. For the latter would recommend the lumbar cut with a mortality of 33% to the abdominal with mortality of 41%.

Svensson.²³ Constant pain; incapable of the lightest work; insisted on operation. Usual lumbar cut; fourteen silk stitches through substance of kidney. Stitches remained in and wound closed without disturbance. Complete disappearance of the trouble without return. Kidney has remained firm, fixed in its position.

In spite of less favorable reports elsewhere about the operation, the writer justly considers his case one

of interest, and sees the cause of failure in the employment of catgut and avoidance of the kidney parenchyma in putting in the stitches.

Lloyd.²⁴ Fixed a movable kidney permanently by the lumbar cut, stripping the capsule back for one-fourth inch, and fastening the freshened part in the wound by very deep sutures.

Newman (Glasgow).²⁵ Capsule cut into and sewed into wound. Two stitches passing into the substance of the wound.

Warfvinge.²⁶ Right side; recovery; cut parallel to the vertebral column; kidney fastened to the muscles and fascia surrounding the operation-wound by a silk thread passing through the kidney.

Smith, J. G.²⁷ Woman, thirty-nine; tumor diagnosed as movable kidney or ovarian tumor. Abdominal incision, found movable kidney. Tried to stitch it subcutaneously, but surface of kidney tore, so scratched it several times with needle and left it *in situ*. The tumor has remained in place, but the patient does not seem much benefited.

Dunning, L. H.²⁸ Woman, forty-four years; lumbar incision; four stitches along each border of the incision, passing through renal capsule and perirenal adipose tissue. Result: kidney movable about one inch laterally; symptoms much relieved; would advise silk for at least half of the stitches.

Other cases are reported by various surgeons (see Bibliography). Slight modifications of Hahn's method have been recommended.

Lucas²⁹ recommends for movable kidney a simple incision to the kidney by a lumbar cut, a perfectly harmless operation. The following cicatricial process will pretty surely lead to fixity of the kidney. If not sufficient, then perform Hahn's nephrorrhaphy of the kidney.

The following case first came to me in the spring of 1887. The patient was very anxious to have an operation, and urged it so strongly that it was with difficulty that she was persuaded to try, first, some palliative measures for her relief. I made a careful study of the case, and had various pads made and applied, all of which she faithfully tried without the slightest benefit. Finally, I decided to perform Hahn's operation, after a consultation, at which the views already presented were urged for and against by the physicians and surgeons present, some favoring further employment of mechanics, probably underrating the woman's suffering, and others advocating an operation for fixation. No one thought nephrectomy justifiable as a first measure.

S. E. C., aged thirty-six, married. Entered the Massachusetts General Hospital, September 19, 1887. Always strong and healthy woman. No history of previous illness. About eighteen months ago, after working, began to have pain in right lumbar region, which she attributed to a strain. Very soon after she became conscious of something moving about in right side of abdomen, every movement of which was accompanied by severe pain. All sorts of apparatus and supports were tried without relief. The pain has been almost constant. Every time she turns over in bed or changes her position at all, she can feel this

thing move, and its movement causes intense pain. She says that she is entirely incapacitated for work, and that her suffering is so great that she will gladly undergo anything that offers prospect of relief. Besides the pain, she complains of some numbness and loss of power in right arm and leg. Otherwise, her health is excellent. There is no history of loss of flesh. Is the mother of several children.

Strong and robust-looking woman. No appearance of impaired health. On examination with patient on left side, there can be felt on deep pressure in right lumbar region a movable body, the size and shape of the kidney. Tumor not painful to touch, but freely movable and painful on movement. The tumor can be displaced very far to the left of the umbilicus and down into the pelvis. Urine normal.³¹

A, Last rib. B, Kidney. C, Crest of ilium. D, Quadratus lumborum.

Operation, September 22, 1887, under ether. Patient on left side. An incision about six inches long along the margin of the *quadratus lumborum* muscle. The edge of the muscle having been found, was drawn to one side and the peri-nephritic fat exposed. This was cut through and separated, exposing posterior surface of kidney. The organ moved up and down freely with inspiration and expiration, undergoing a displacement of about two inches, making it very difficult to apply the sutures. Sutures of silk were passed through the capsule of the kidney by means of round needle, without entering the kidney substance. Four of these stitches were taken and the edges of the wound drawn together, with surface of kidney approximated to their inner surface. Wound then closed tightly with superficial stitches. Iodoform gauze and salicylic cotton dressings (see cut). Rapid convalescence, with no rise of temperature. The stitches which were passed through the capsule were removed October 7th. During the convalescence there was some pain in the region of the kidney and in the wound. There was from the first relief of her symptoms, which has continued up to the present time (May 20, 1888). She was kept in bed till Messrs. Leach & Greene had made a special pad. With this she was allowed to get up, October 30th. She returned home, and has been perfectly well ever since.

June 1, 1887, she wrote to me: "I came home from St. Margaret's altogether discouraged. . . . I am miserable and good for nothing in the world,

and have so much to do that I have not strength to accomplish that I am anxious to risk any peril for the hope of getting well."

February 29, 1888, she wrote: "I am splendidly well."

In this case, mechanical treatment was tried patiently and thoroughly till the fact was clearly demonstrated that there was nothing to be gained by it. The operation of fixation has been far more successful than I dared hope. I believe that the kidney has been permanently fastened in place by cicatricial-tissue adhesions, and that by this time it has been firmly and permanently fixed in its new position.

The kidney was not fastened into its normal position, for it was impossible to fix it high enough, but it is about two inches lower down. I believe, with Landau, that it is extremely difficult, if not impossible, to bring the kidney, especially the right, into its normal position, but I do not see that it is any disadvantage to have it brought conveniently low down.

It seems to me that the opinions expressed by the authorities already quoted present most fairly the present aspect of the best treatment in these cases; namely, that in many cases, if not in most, no interference is demanded or justified, beyond the application of a pad. In some cases, even this is not necessary, as there are no symptoms. If the symptoms are unendurable, then nephrorrhaphy can be done with little danger to life, and with, as it seems to me, a very good chance of permanent recovery, or, at least, enough lasting benefit to justify the operation. Finally, if fixation has not followed, we can, as a last remedy for unbearable pain and distress, resort to removal of the offending viscus.

OBSERVATIONS ON FORTY-FIVE CASES OF FLAT-FOOT WITH PARTICULAR REFERENCE TO ETIOLOGY AND TREATMENT.¹

BY ROYAL WHITMAN, M.D.

Surgeon to the Orthopedic Department of the Boston Dispensary.

I AM inclined to think that the frequency of troubles caused by overstraining the arch of the foot is not appreciated, and that the condition is not generally recognized, because nearly every patient whom I have treated for this affection, many of whom presented the typical appearances of flat-foot, sometimes to an extreme degree, were taking, or had taken for long periods, internal remedies on the supposition that the symptoms were caused by rheumatism. Some observations on the etiology of the affection, with a more detailed account of its treatment than can be found in surgical or orthopedic works, may prove of interest to those who may be called upon to treat it.

The gross appearances and symptoms in acquired flat-foot have been sufficiently well described by various writers. In a typical case they are as follows: The arch of the foot is lowered; or completely broken down, so that the entire sole rests upon the floor; on the inside of the foot the slight normal outward curve from the heel to the head of the first metatarsal is replaced by a bulging inwards, most prominent below and in front of the internal malleolus. The foot seems broader than usual, and the internal malleolus is abnormally prominent; when the patient stands the entire foot seems displaced outwards on the leg, this being especially marked when looking at it from behind; the tissues on the inside of the arch and ankle seem thickened and congested; prominent veins and increased moisture of the foot are often noticed; in walking the feet are turned out more than usual, and a short awkward step is sometimes observed (see plates 1 and 2); the subjective symptoms are various, the most constant being pain especially after long standing or walking, most often about the inside of the ankle, sometimes shooting up the inside of the leg, or in the outside of the ankle, the ball of the foot, the heel, or middle of the sole; as patients express it, the foot

seems heavy, and to have lost its spring; a symptom which I have not seen described is often complained of, a stiffness in the foot; for example, after sitting for any length of time, or on rising in the morning, the feet seem stiff and unmanageable when attempting to walk, the sensation lasting several minutes.

On manipulation — pressure over the astragalo-scaploid articulation is painful — forcibly turning the fore-foot out or in, causes pain here, sometimes also just in front of the external and internal malleoli; forced flexion or extension of the medio-tarsal joint is often attended with pain. These symptoms may, and most often do, come on slowly, and are of long duration, aggravated by overwork, relieved by rest; but they may appear suddenly, as in cases where there has been a gradual breaking down of the arch, a slight unnoticed injury may result in great pain, accompanied by redness and swelling; really, a sprain occurring in a weakened foot.

Fig 1.

Drawn from a cast of the flat-foot, showing the outward displacement of the foot on the leg.
A, the weight-bearing centre of the astragalus, which should normally be in the line of traction of the *Tendo-Achillis*; E, internal malleolus; F, head of the astragalus; G, external malleolus.

It must be remembered that in old flat feet the displaced bones constantly rubbing on each other, pressing on their over-stretched ligaments, may induce a low grade of inflammation, as shown at autopsies by eroded cartilages, ligaments and porosities of the bones. Such cases might easily be mistaken for chronic rheumatism, if the deformity were slight, especially if, as sometimes happens, but one foot were affected in a person subject to rheumatic inflammation in other joints. The symptoms, too, do not at all correspond with the degree of deformity. Many persons with complete flat-foot have no trouble, while others who

¹ Read at the meeting of the Surgical Section of the Suffolk District Medical Society, April 4, 1888.

are practically disabled by it show but a slight flattening of the arch.

Many flat feet can, by manipulation, be nearly or quite replaced in their normal position, others only partially.

In order to understand the etiology of the affection, and that the reasons for the treatment which will be recommended may be made clear, it will be necessary to describe some of the anatomical peculiarities of the foot.

Fig. 2.

Anterior view, showing the eversion of the fore-foot. The line A B, drawn through the axis of the leg, should normally fall through A, C, D.

E, internal malleolus; F, head of the astragalus; G, external malleolus.

The astragalus, when the foot rests upon the ground, is usually held firmly between the tibia and fibula, permitting almost no movement except as a hinge-joint, the lateral movements taking place in the joint between it and the os calcis, to which it is attached principally by the interosseous ligament. When the foot bears weight the tendency is to abduction, that is, a slight flattening out of the arch, a turning out of the toes, and a tilting of the os calcis over towards the inner side, its anterior extremity turning slightly inwards and downwards, while the point of the heel turns slightly outwards.

There is a slight rotation of the astragalus forwards, downwards, and inwards, so that its anterior extremity, or head, articulating with the scaphoid, becomes more prominent: also a broadening and slight lengthening of the foot. These movements, which normally take place to an appreciable extent, are exaggerated in a foot whose muscles are weakened and ligaments stretched from overwork; thus the anterior extremity of the os calcis falls inwards and downwards, the bone tilts over so that its

external tubercle is raised to a considerable angle with the floor. This change would affect the level of the astragalus in its relation to the leg bones, were it not for the fact that its increased rotation allows its outer margin to sink down into the interosseous fossa, pressing before it the interosseous ligament, a movement which depresses its external and raises its internal border. The head of the astragalus, in its exaggerated rotation, presses inwards on the internal lateral, and inwards and downwards on the calcaneo-scapoid ligaments, while its axis which should be in a line with the second toe, may point inside the great toe. The distance between the internal malleolus and the sustentaculum tali is increased, and the external malleolus comes in close proximity to the os calcis, pressing on the external ligaments. At the same time the flattening and abduction of the foot strain, to a certain extent, all its minor ligaments. After a time the displacement may become permanent. Then may follow changes in muscles, ligaments, cartilages and bones.²

In order to ascertain the amount of rotation of the astragalus, and the expansion of the heads of the metatarsals under weight, a series of comparative measurements, of normal and flat feet, in children and adult males and females, were made, with the following results:

A, Length of foot.
B, Distance between the external malleolus and the head of the astragalus, the foot resting easily on the floor at a right angle with the leg.
C, The same measurement when the foot sustains the entire weight of the body.
D, Distance between the head of the first and fifth metatarsals.
E, Same measurement under weight.
Measurement in Millimetres.

cupation, in which he had been engaged for five years, bell-boy in a hotel, a most trying one for the feet, may have been in his case a more important factor than inheritance.

I am not now speaking of the negro type of foot, long, flat, with projecting heels, but of cases that would be considered typical illustrations of the deformity. In one family I found three generations of flat feet. The child, however, showed marked evidence of rachitis, an affection in which it is usually present.

HIGH HEELS.

Mayo-Collier⁶ contends that the wearing of high heels is the cause of flat feet, quoting Little: "a slight degree of atonic valgus is common in girls, especially in those of the upper and middle classes." "Why not in the less fortunate and badly-nourished females of the lower classes? Because the high heels are less prevalent with them." My experience leads me to consider "atonic" flat-foot as especially the affection of servant-girls, often badly nourished, and obliged to be almost constantly on their feet. This class do not wear especially high heels; they do wear ill-fitting boots, with narrow soles, which compress and deform the toes, and rest their feet with cloth boots and slippers, which give no support to the arch; and in this class the tired feeling and dull ache in the feet, so characteristic of an over-strained arch, is very common.

Again, raising the heel in one of these cases does not increase the deformity. On the contrary, if the bare foot be placed squarely on the floor, and the body be inclined forward so that more weight is brought on the "waist" of the foot, it will be increased.

CONGENITAL OSSEUS MALFORMATION.

It has been suggested, because flat-foot occurs in robust persons, and because changes in the bone have been found, too great to be accounted for by mechanical causes, that an original osseous malformation would best explain the origin of the affection.⁷ The affection does, it is true, occur in robust persons, but if one of these patients be questioned, it will be found that he dates his symptoms from some strain or from some peculiarity in his occupation. As an illustration, a healthy, well-developed young man was sent to me last week, presenting a very considerable flattening of the arch of one foot, accompanied by pain, swelling, and muscular spasm. I found that his occupation as a bookbinder compelled him to stand all day on the affected foot, while he worked a treadle with the other. Again, I should not admit that the deformities of the bones, as described in the published autopsies, were too great for explanation on mechanical grounds. They are no greater than those found in other bones under similar conditions.

Lastly, the number of autopsies on flat-foot is too small to support any peculiar and improbable theory as a general explanation of the affection. It may be that these different theories have resulted from a failure to recognize the varying types of the affection. One observer sees cases or makes a dissection of a foot showing great relaxation of ligaments, and concludes that all cases result from lax ligaments. Another meeting acute cases where, as in acute affection of other joints, muscular spasm and contraction are prominent features, considers muscular spasm, con-

traction, atrophy or paralysis as exciting causes. While another accounts high heels responsible for the symptoms which he notices.

THE OVERWORK THEORY.

It seems to me that the most reasonable explanation of its cause is that of a disproportion between the weight the foot is called upon to bear and the ability of its muscles and ligaments to sustain it, a simple breaking down from overwork.

(To be continued.)

New Instruments.

AN INSTRUMENT FOR TAPPING OVARIAN CYSTS.

DEvised BY H. E. HEYDECKER, HARVARD MEDICAL SCHOOL.

The accompanying cut represents an instrument for tapping ovarian cysts, which was shown at the last meeting of the Suffolk District Medical Society.¹

It is a modification of Sir Spencer Wells's abdominal trocar, and was especially designed for the use of Dr. John Homan in his operations for the removal of ovarian tumors by laparotomy.

The instrument consists of a canula (a), at one end of which is a cutting edge (b); at the other end (c) a curved tube is attached, which communicates with a long rubber delivery pipe.

Inside the canula is a close-fitting tube (d), which is moved by the lock knob (e), and which acts as a guard to the cutting point (b). Outside the canula is another tube (f), which slides upon the canula and is clamped in position by the thumb-screw (g).

To this tube is attached a shoulder (h), which, sliding down upon the ends of the springs (i), holds the cyst-wall firmly.

The springs (i), when depressed, fit into grooves on the side of the canula, and are held in position by the end of the sliding tube (ff). When thus depressed, these springs are flush with the surface of the canula. The method of using the trocar is as follows:

The cyst being exposed by an incision through the abdominal walls and the peritoneum, the cutting end of the canula is plunged into the cyst-wall until the end of the sliding tube (ff) reaches the cyst and is stopped. The canula is then pushed on until the springs are set free inside the cyst.

The guard (d) is now slid forward, to prevent the cutting point injuring the abdominal viscera.

⁶ Flat-Foot, by M. P. Mayo-Collier, *Lancet*, September 4, 1886.

⁷ Stokes, *Annals of Surgery*, Oct., 1885.

¹ The cut represents the instrument two-thirds the actual size.

The shoulder (*h*) is then pressed down against the ends of the springs (*i*), thereby engaging the cyst-wall between the ends of the springs and the shoulder, and is clamped in that position by the thumb-screw (*g*). By this means all fluid is prevented from escaping between the cyst-wall and the sides of the canula.

The fluid in the meantime is running out of the cyst through the delivery tube, and the cyst-walls being firmly held by the springs, the emptying sac is gradually drawn out from the abdominal cavity through a small opening.

The advantages claimed for this instrument are:

(1) That through the almost automatic action of the springs, the cyst-wall is firmly held as soon as the trocar is introduced, and no time is lost in drawing the cyst-walls up on the sides of the tube with a pair of forceps (which is necessary in order to fasten them when using the old form of trocar).

By this means the danger of the cyst slipping back into the abdominal cavity and discharging its contents into the peritoneum is also avoided.

(2) That through the intervention of the shoulder (*h*), fluid is prevented from escaping between the cyst-wall and the canula, and flowing back into the opening in the abdomen.

(3) That it affords a better and more easily obtainable hold upon the cyst than can be secured by cyst-forceps.

The instrument was made by Codman and Shurtleff, and is now being used by Dr. John Homans.

FOURTH DAY.—FRIDAY, MAY 11TH.

GRADUAL DILATATION OF OESOPHAGEAL STRICTURES.
by THOMAS P. DAVIS, Pittsburg.

Oesophageal strictures are so serious in their nature that only within a few years has any method for procuring permanent relief been attempted; and now he desires to call attention to a more conservative treatment than that in use. Cicatricial stricture may be caused by direct injuries or by foreign bodies passing through the oesophagus; syphilis has also been assigned as a cause, but the most common etiological factor of destruction of the tissues is the swallowing of caustic substances. Many such cases have been reported since these articles have been introduced more generally into domestic use. He reported three cases of his own:

CASE I. A boy had swallowed some corrosive substance unknown to his nurse. When seen, four hours afterwards, he had been "vomiting and slaverling thick saliva, tinged with blood, and his mouth was fiery-red." Oil and demulcents were freely given and retained, and his mouth rapidly healed. After five weeks he was emaciated, was having attacks of vomiting, and rejecting the smallest quantities of food. Oesophageal stricture was diagnosed on this visit, and a No. 2 flexible catheter was introduced into the

stomach with much difficulty, owing to a dilatation above the stricture, making the opening difficult to find.

Immediately after the operation the child could swallow a little milk. These tubes were inserted frequently, the size being gradually increased, to avoid giving pain. After six weeks the improvement was so great that the parents were allowed to use the bougies, and in five months a No. 2 rectal bougie was used. This has been used at intervals since, till all marked symptoms of stricture have disappeared.

CASE II was seen a few moments after drinking from a can of concentrated lye. Her tongue, cheeks, and fauces were white, and there was bleeding from the mouth. Vinegar was given, followed by table oil, which, being rejected, milk was given. After a week, the largest-sized English catheter was introduced, but it was necessary to decrease the size, till, in the course of a month, only the smallest could be used. The treatment was afterward continued more successfully until a grape-seed was lodged in the stricture, which was very difficult to remove. Again, a too rapid dilatation caused the formation of an abscess, but, six months after the accident, a rectal bougie could be introduced. Now, after seven years, deglutition is not impaired, though the size of the oesophagus is not normal.

CASE III differed from the others in showing evidences of ulcers in the stomach. These healed in time, the child recovered in six months, and, after three years, is in good health.

He prefers the use of the common English catheters, straightened out, as they are more easily obtained and are more suitable for a gradual dilatation than anything else on the market.

The writer remarked (1) that he could concur in the opinion that stricture is produced by a tonic spasm, continuing for several days, the clogging of the passage by mucus or food explaining, to his mind, the difficulty in inserting the bougie.

(2) Dilatation of the oesophagus above the stricture is prevented by promptly introducing the bougie.

(3) The second case shows the contrast between the rapid and gradual modes of treatment.

DR. PANCOAST, of Philadelphia, observed that no method but gradual dilatation should ever be used. This principle holds in stricture of the urethra, as well as in that of other mucous ducts; and in stricture of the urethra dilatation should be exhausted before the performance of urethrotomy. In a case of his own, the patient swallowed a wineglassful of sulphuric acid, and suffered from an extensive and serious stricture. He feels sure that spasmodic stricture does exist, as he has observed it himself, in which case the food was retained in the oesophagus until the spasm ceased. The secret of the success of the rat-tail bougie exists in the fact that the larger portion, being held above the point, is more readily directed into the proper channel.

SACRO-ILIAC TUBERCULOSIS,

by WELLER VAN HOOK, Chicago.

Sacro-iliac disease, which is essentially a strumous or tuberculous affection, and whose pathology is identical with that of tuberculosis of other joint surfaces, is treated according to the same general principles that govern the treatment of the same disease elsewhere.

¹ Concluded from page 580.

Absolute rest should be enforced, and to obtain this the patient should lie on the back, and not on the side, for the latter posture causes a considerable strain on the joint surfaces of the sacro-iliac articulation, and thus to a certain extent defeats the purpose of the treatment. This, together with suitable supporting and nourishing measures, may effect a cure in recent cases; but when the inflammation has proceeded to suppuration and abscesses form, operative interference will be necessary.

An abscess may point and break externally, or if it is situated more deeply, and the anterior surface of the joint is involved, it may open into the pelvic cavity, and thence pass into the thigh or to the perineum.

If abscess is on the outside, an incision directly over it may give exit to the pus; it may be necessary to remove the diseased portion of bone with a gouge. But when the trouble is situated further forward, an incision about two inches long should be made over and just above the posterior inferior spinous process of the ilium, and the tendinous attachments pushed aside with a blunt instrument. The diseased bone can be completely removed through this wound with a chisel and a gouge.

It should have been mentioned that counter-irritation and extension should be practised in recent cases, as well as complete rest.

GENERAL SESSIONS.

FOURTH DAY, FRIDAY, MAY 11TH.

Meeting opened by DR. A. Y. P. GARNETT, President. The address on

STATE MEDICINE,

was delivered by DR. H. P. WALCOTT, of Boston, who urged the necessity of States, General Government, and Municipalities taking additional precautions for the prevention of disease, and demonstrated how by measures such as are adopted by the Massachusetts State Board of Health, the spread of contagious disease could be diminished or reduced to a minimum.

In the report of the standing committee on Meteorological Conditions, DR. N. S. DAVIS, Chairman, there were presented:—

(1) A summary of facts gathered, concerning all appreciable meteorological conditions, coincidentally observed and recorded in different parts of the country.

(2) The efforts made to determine how far these facts show any constant relation of one series of facts to another.

(3) A summary concerning the prevalence of a limited number of acute general diseases, more particularly typhoid fever.

(4) A critical examination instituted to determine what uniform coincidence, if any, can be traced between the more important meteorological conditions and the prevalence of disease.

The following questions were submitted:—

(1) Is it probable that the free and albuminoid ammonia, when existing in the atmosphere in excess, compared with the amount of ozone and hydrogen peroxide, can constitute the pabulum for the rapid development of either pathogenic germs or ptomaines, and thereby afford an explanation of apparently simultaneous attacks of some epidemic diseases in several persons in the same city or district, yet without any other traceable connection with each other?

(2) Do the well-established facts attending the development or propagation of typhoid fever and cholera justify the inference that the specific causes require active propagating pathogenic force, only exterior to the body and in connection with soil water?

(3) May such specific causes continue to propagate and retain their pathogenic force indefinitely, exterior to the body, or do they pass one stage of development in the living body and another exterior to it?

On motion, the committee was continued.

DR. QUIMBY read the report of the special committee on Criminality of Feticide and Measures for its Prevention. The adoption of the report was opposed by a number of members and on motion, laid on the table. The report of the special committee on Duties commonly Exercised by Coroners, read by DR. MARCY, was adopted.

On motion, a resolution was adopted, urging upon Congress the necessity of immediate passage of Senate bill No. 2,493, to perfect the quarantine service of the United States, which bill has passed the Senate and is now pending in the House of Representatives, in order to make provisions for protection against the introduction of contagious diseases before the approaching summer.

A motion was made to take from the table an amendment to the By-Laws, which had been so placed at the last annual meeting, and adopt it. The amendment had been proposed at the last meeting by Dr. Seiler, and divided the Section of Ophthalmology, Otology and Laryngology into two sections, one on Ophthalmology and the other on Otology and Laryngology. The motion was carried.

DR. LOVE moved that the report made by the committee on Feticide, etc., be taken from the table and referred back to the committee. After considerable discussion Dr. Love accepted an amendment to refer the report to the committee on State medicine, in which form the motion prevailed.

DR. QUIMBY presented a resolution recommending the appointment of a committee, to consist of one member from each State, whose duty it shall be to devise the best means to secure adequate legislation to provide for examination, charter colleges, and provide for higher medical education. On motion, the resolution was tabled.

The following resolution was adopted: "That the American Medical Association approves of the movement looking to the celebration in Washington, in 1892, of the four hundredth anniversary of the discovery of America by Columbus, and the establishment there of a museum of the arts, industries and antiquities of the three Americas; and the Association hereby requests Congress to pass the necessary legislation appropriate to this end." Carried.

THE SECRETARY read the reports of secretaries of the various Sections and announced the foreign delegates.

After a vote of thanks to the Chairman and the profession of Cincinnati, the Association adjourned.

—A prisoner in an English jail recently committed suicide by the novel manner of cramming a piece of cloth down his throat with a wooden spoon. The medical evidence, however, showed that the spoon could not have been pressed so far down with the hand, and that the man lay face downward and pressed the bowl of the spoon against the floor.

THE NEW YORK ACADEMY OF MEDICINE.
SECTION ON NEUROLOGY.

STATED MEETING, May 11, 1888.

DR. W. H. THOMSON read a paper on

DIPHTHERITIC PARALYSIS.

In commencing he referred to what he termed the post-latent stage of the acute infectious diseases. Upon the antecedent latent stage, or period of incubation followed the stage of development, the termination of which was taken for granted by the text-books to coincide with the subsidence and disappearance of all the characteristic signs of the disease itself, and with the restoration of the disordered functions of the body to their normal state. He had long been of the opinion however, that in this class of affections there followed a latent stage, specific to each disease in its characters and of equally specific processes and duration, so that not only must a post-latent period be predicated of them as necessary to their real course, and always preceding final recovery, but the fact be also taken into consideration that in each the specific latent processes are often of as much practical importance as regards the matter of treatment as any of the outward manifestations of the stage of development itself. If this was true, when certain disorders arose during the so-called convalescence of the patient, instead of regarding them as sequelæ, and therefore of a more or less accidental character, we should look upon them as much parts of the original disease as the eruption of an exanthema. Thus, scarlatinous nephritis ought not to be called a sequel of scarlet fever, for we had no right to forget that the child still has scarlatina and the kidneys are yet to be heard from, though the patient may have returned to play for two weeks after his apparently mild and temporary illness.

The frequent severity of many of these so-called sequelæ, in comparison with the light symptoms of the stage of development, ought also to suggest, he said, that instead of having only traces or after-effects to deal with, we had the original complaint still in all its power, and that in these cases its most active workings were during this third period of the disease. Having spoken of what he regarded as the post-latent stage of scarlatina, typhoid fever, measles, and ague, he stated that what he wished to maintain was that all diseases which depend upon an infection of the system by a self-multiplying agent are divisible in their life-history into three stages; namely, (1) the pre-latent or incubation period; (2) the development or manifestation period, and (3) the post-latent period, which latter is not a sequel of the preceding two, but a necessary and integral stage of the whole process, with its own specific characters, and therefore, its own specific dangers, and probably dependent in some cases upon the addition of new special elements in the morbid process. Diphtheritic paralysis was, therefore, by no means exceptional in affording us an instance of an infective disease apparently, but only apparently, getting well, and then being followed, perhaps after a period of some weeks, by the development of very formidable symptoms. The intensity of these symptoms in many cases so much exceeds the preceding signs of diphtheria that he had several patients brought to him in whom no such antecedent was suspected. Hence it was clearly a post-latent stage development, for it rarely manifested itself till the second week

after the ordinary course of the disease; in most cases not coming on till the third week, and in many not till the fourth week, or were longer. At first sight diphtheritic paralysis appeared somewhat analogous to hysterical. Thus, it often happened that while it was invading new tracts of nervous distribution it was leaving those first attacked. This superficial resemblance with hysteria, however, ended here, for no disease had in reality less of the characters of functional and more of those of the organic paralysis than it manifested. On the other hand, in contrast with organic paralyses, it began generally with just the signs with which the worst organic forms ended; namely, with apparently bulbar symptoms. For a long time the early implication of the palate was universally ascribed to the local influence of the antecedent exudation in the throat; but this view was negatived not only by the fact that the paralysis bears no special relation to the extent or duration of the previous angina, but also by the fact that paralysis of the palate and dysphagia are the most common parietic symptoms in those patients in whom the original seat of the disease was not in the throat at all, but in some other parts of the body.

Having stated that his object was rather to discuss the nature of diphtheritic paralysis than to enumerate its various clinical manifestations, he went on to remark that the coincidence of motor and sensor paralysis in limited localities which were yet supplied from both sides of the brain and cord would indicate that the lesion was peripheral and not central. It was true that we often had only a motor or only a sensory local paralysis in diphtheria, but in the palate it was frequently the reverse, both arches being equally relaxed and equally insensitive. On the other hand, some of the patients of the next most common manifestation of diphtheritic paralysis, namely, that of the power of accommodation in the eye were rather puzzling to explain on the hypothesis of peripheral rather than centric origin. As in other examples of ophthalmoplegia interna the slight loss of accommodation with preservation of the light reflex was a sign of a central lesion, it seemed to be difficult to attribute diphtheritic cycloplegia to a local affection of the ciliary muscle, except that in other paralyses of the third nerve not diphtheritic it was rare to see one limited to the ciliary branch alone. It was curious, also, that the power of contracting the pupil in efforts at accommodation was sometimes preserved and sometimes absent after diphtheria.

In about half the cases of palatine palsy the limbs became in time involved, and the legs both before and more extensively than the arms. The leg movements were quite unlike those of spinal paraplegia, and instead of being stiff and spreading, were more like those of hysterical paralysis in dropping heavily to the floor. Dr. Thomson referred briefly to other seats of paralytic trouble, and then stated that the exemptions of diphtheritic paralysis were quite noticeable and peculiar. Besides the nerves of hearing and of sight we had a striking exemption of the vasomotor and trophic nerves. The skin of the paralyzed parts was neither glossy, oedematous, or mottled, nor the seat of ulcerations or erosions; though occasionally there was a more or less transient atrophy of some muscles. The electrical relations were sometimes unchanged. Oftener, however, when the motor disturbances had been prolonged, faradic excitability

was much diminished or lost, and the muscle phenomenon of the reaction of degeneration was present. It was in these cases that we came the nearest to signs of centric implication in slight weakness of the sphincters of the bladder and rectum, especially of the former.

The most characteristic, that is to say invariable, change of diphtheritic paralysis was absence of the knee-jerk. This phenomenon not only accompanied the paralysis, but it belonged to diphtheria by itself; for, according to Bernhardt, it occurred in about two-thirds of all cases of diphtheria which have no paralyses of any kind. The existence of a post-latent stage in this disease was thus demonstrated, even if we did not have paralysis; for, according to Bernhardt's observations, its most usual time of development in non-paralytic cases was in the second week, although it sometimes begins at the end of the first. Dr. R. L. McDonnell, of Montreal General Hospital, however, had published records of eighteen cases of diphtheria admitted to his wards, in ten of which the knee-jerk was absent at the time of admission, and while they were suffering from the first symptoms of the disease. From his observations on these cases he arrived at the following conclusions: (1) In a considerable number of cases the knee-jerk is lost from the beginning of the disease, and this affords a valuable means of diagnosis of the nature of the throat affection; (2) absent knee-jerk at the beginning has no influence on the prognosis.

While Dr. McDonnell's experience was probably exceptional, the fact remained that this symptom was of such constant occurrence in diphtheria, and was so significant in itself from its relation to other nervous diseases of the nature of the morbid process in diphtheritic paralysis, that it took the first rank in the consideration of the true pathology of the affection.

Before going further Dr. Thomson summed up his conclusions as to the pathology of diphtheritic paralysis from its clinical features alone, as follows:

(1) That it is due to a peripheric and not centric nervous disorder, because it is so difficult to conceive of the central nuclei being primarily affected in many cases of diphtheria without their closely contiguous or associated nerve-centres becoming also involved, as they are in all other nervous affections where the centres in question are affected.

(2) That it is not due to any inflammatory infection of the peripheric nerves. The great clinical feature of neuritis is pain, and absence of pain is the distinctive feature of diphtheritic paralysis.

(3) That from the start it is characterized by paralysis of reflex impressions. This, of itself, is conclusive against a primary inflammatory element, and it is further supported by the absence of signs of implication of the vaso-motor nerves, which are so sensitive to inflammatory irritation. This early abolition of reflex movements is not only shown in the patellar reflex, but elsewhere even more strikingly. Often not the slightest attempt at gagging will follow the most prolonged titillation of the palsied palate, and the epiglottis, when affected, may be fingered without the least protest.

As to the pathological anatomy of diphtheritic paralysis, we owe to Déjerine the first conclusive demonstration that this affection has for its anatomical basis a change similar in all its essential features

to the changes found in multiple neuritis from any cause. Dr. Thomson said that he did not regard that anatomical change in nerve-fibres to which the term parenchymatous neuritis is applied as a neuritis at all in the sense that it is caused by a true inflammatory process, but rather as a primary degeneration of the nerve-elements quite distinct from inflammation. Interstitial neuritis was the only true neuritis, as it is accompanied by a cell infiltration and the other characteristics of all inflammatory processes. In a recent publication Déjerine had described the typical microscopic appearances of descending Wallerian degeneration, without any signs of interstitial inflammation, in a case of diphtheritic paralysis. Muscular degenerations, as might be expected, accompanied, although in varying degrees, the nerve-lesions of diphtheria. Such alterations had been demonstrated most in the palate, but also in other regions, and especially in the heart. This organ, however, suffered from more than one condition in diphtheria, both in the early and in the post-latent stages of the disease.

Finally, the interesting question presented itself, What is the special agent present in the system which causes diphtheritic paralysis? In the first place, it could hardly be the original infective material which was the cause of diphtheria, because that belonged plainly to the class of agents which occasion communicable diseases; in other words, it was a living self-multiplying organism. Diphtheritic paralysis only came after there was nothing more to catch from the patient (generally weeks after the infective agent had done its work), and was no more catching than any other paralysis. On the other hand, our knowledge of the action of micro-organisms was sufficiently advanced now for us to know that some of them evidently cause disease by generating definite poisons or ptomaines, which are absorbable into the blood, and then act there just as other poisons act; some of them as even arsenic does, causing multiple neuritis of a disconnected and yet selective kind. This rendered it quite conceivable that a ptomaine might follow upon the changes which the diphtheritic process set up in the organism, and thus produce all of its characteristic symptoms. The special tendency of diphtheritic inflammation to cause necrotic and gangrenous lesions lent a further support to this surmise.

As the processes of Nature were never wholly exceptional, but often were reproduced in different yet analogous forms, it was possible to suppose that the working of the diphtheritic organism might in certain cases prepare the way for some subsequent process in the body by another organism, when the conditions for its growth had been fulfilled by the antecedent presence of the diphtheritic agent, and that it was during this subsequent process that the poison which works such mischief in the venous system was produced. This surmise was rendered more probable by the remarkable account of Boissarie, cited by Gowers, of an epidemic in a certain district of Paris, where there were observed a series of cases of severe diphtheria and at the same time a series of cases of paralysis of the palate, eyes, limbs, etc., exactly like that which occurs after diphtheria, and accompanied by albuminuria. Yet in these cases of primary palsy there was no history of preceding sore throat, and, strange to say, in several of them distinct diphtheria followed the paralysis, which diminished during the throat affection; indicating that the poison of the paralytic

disease was of a different origin from the virus of the diphtheria. Hence it seemed likely that under certain circumstances its producer could exist and form its specific ptomaine without having the diphtheritic agent to prepare the way for it. The late researches of Pitres and Villiard, on peripheral neuritis occurring after typhoid fever, with instances of the same paralysis of the palate and of accommodation occurring after that disease as after diphtheria, further lent color to the surmise that we may have an independent origin from some successive organism of the paralyzing poison, which develops generally after diphtheria, but may also do so after typhoid, and perhaps after other forms, or occur independently, as in Boissarie's cases.

DISCUSSION.

DR. A. JACOB said that there were undoubted cases of central origin on record, and a few cases of ataxia even had been observed. He believed that Dr. Thomson was right in assuming that the paralysis was not to be taken as merely a sequelæ of diphtheria, but rather as really part and parcel of the disease. If there was any affection which ran an indefinite course, it certainly was diphtheria; this course sometimes extending over many months. One difference between this and the other contagious diseases was that, once having had it, the subject was all the more liable to subsequent attacks. In many instances it seemed to him that these repeated attacks simply showed the continuous presence in the system of the disease, which might be hidden away in the tonsils or the lymph-bodies, and likely at any time to break out afresh.

As a rule, the paralysis first appeared in the fauces, affecting deglutition, and then successively in the muscles of ocular accommodation and of the extremities. Finally, there might be respiratory paralysis, which often proved fatal. This order could never be relied upon, however, and in making a diagnosis in cases where there had been no throat symptoms, one of the main points to be depended on was the fact that in diphtheritic paralysis only a comparatively small number of muscles were usually affected at the same time. Another point was the fact that the sphincter was never, or almost never, involved.

He then went on to say that paralysis not infrequently came on during the acute stage of diphtheria. In heart-failure, which was so common an occurrence in this disease, there was no doubt a failure of the heart-nerves, either the sympathetic or the pneumogastric. This was an accident liable to occur in any case of diphtheria, and he had therefore always insisted on the free administration of alcoholic stimulus, and cardiac tonics from the very first. After symptoms of heart-trouble had once appeared, it was usually too late for such remedies to be of much service. Respiratory paralysis was about as fatal as heart-failure, hence the most energetic measures were called for to combat it, and strychnia and electricity should be pushed to the utmost possible extent in such cases.

DR. ANDREW H. SMITH said that it seemed to him very remarkable that we should so frequently have recovery from diphtheritic paralysis when the anatomical lesions of the condition were so marked. The paralysis had also always been somewhat of a stumbling block to him in trying to accept the hypothesis that diphtheria is originally a merely local disease. He had no doubt that there were cases of diphtheria in

which no membranes ever appeared, and the fact that instances were on record in which diphtheritic paralysis occurred without any previous throat symptoms certainly went to sustain the idea that diphtheria is essentially a general disease; while the membrane was only an indication of it, just as the erythema of scarlatina was the outward manifestation of that disease. In scarlatina and the other exanthemata the eruption did not constitute the disease.

Dr. Smith then referred to the case of a child whose mother had diphtheria, in which the diphtheritic membrane appeared, not in the throat, but in the groin, where the skin had become chafed. It was also remarkable, he went on to say, that in cases of diphtheritic paralysis not preceded by the appearance of membranes in the throat the paresis usually began in the fauces. This would seem to indicate a peculiar predilection of diphtheria for this region, aside from the simple deposit of membranes there.

DR. L. PUTZEL said that he did not understand exactly what Dr. Thomson meant by the post-latent stage of diphtheria. This disease was different from scarlatina because in scarlatinal nephritis the bacterium which was the exciting cause of the acute affection still remained in the system. It seemed to him more probable that the acute attack of diphtheria left the nervous system in a weakened condition, in which any slight cause might bring on paralysis. As regards the fact that paralysis usually made its first appearance in the fauces, the reason for this seemed to be because the throat was so much affected in the acute attack. As to those rare cases in which paralysis occurred without any previous local trouble, he was not aware that a sufficient number of such instances had been observed to base any conclusion upon.

DR. MALCOLM McLEAN described a very severe and prolonged attack of diphtheritic paralysis occurring in his own person a few years ago, in which, he said, more muscles and a greater extent of cutaneous surface were affected than was usual in cases which recover. It lasted for four and a half months, and involved the muscles of respiration as well as those of the throat, and of both the upper and lower extremities, but did not affect the sphincters. With the paralysis there was marked hyperæsthesia. On the fourth day of the acute attack of diphtheria which preceded the paralysis, symptoms of heart-failure appeared, and the heart continued weak throughout the course of the subsequent paralysis. On one occasion the pulse, the ordinary rate of which was 52, fell to 32, afterwards suddenly rising for a time to 160, and this was accompanied by a most violent attack of angina pectoris, which nearly proved fatal. The practical point, which Dr. McLean said he wished to impress, was the necessity in such cases of the most absolute rest. In his own case the treatment consisted for a long time of faradization and galvanism, and in order to receive the electricity he was taken in a carriage to the office of the physician who applied it. Although this was done with the greatest skill, however, he only grew worse instead of better, except as regards the original paralysis of the fauces, which had greatly diminished. At length so great was the pain and distress which he suffered that he determined to take absolute rest in bed; and as soon as he adopted this course he began to improve. He remained in bed for a month, and the result was so satisfactory that he became convinced that in these severe cases unless this

absolute rest was insisted on, no other treatment would be of any avail.

DR. S. SEABURY JONES mentioned a case of tabes dorsalis, which occurred in a druggist who had received a wound in the hand while assisting at a tracheotomy performed on a diphtheritic patient, the paralysis commencing in the injured hand. In such cases, according to Trousseau, the paralysis sometimes, however, attacked the throat first. He then referred to a case resembling bulbar paralysis, which occurred in a woman whose child had diphtheria, but who did not, so far as could be ascertained, have any membranes herself, although she complained of sore throat. It was wonderful with what clearness and minuteness Trousseau had described all the characteristics and varieties of diphtheritic paralysis, and there was no question in his own mind that the lesion might be either central or peripheral.

The chairman of the Section, DR. W. R. BIRDSALL, said that as regards the pathology of diphtheritic paralysis, he also believed that, while in many instances there was simply a neuritis, cases of undoubted central origin sometimes occurred. In the latter, however, the central lesion was apt to give rise also to peripheral degeneration. In adults diphtheritic paralysis was relatively more frequent than in children, and it very often occurred in cases in which the original attack of diphtheria was very slight. As to the matter of heart-failure, it was a question whether the trouble was of the same nature as the paralysis observed after the acute attack, or whether it was merely functional in character. A point against its paralytic origin was the early stage at which it occurred. As to the etiology of diphtheritic paralysis, it seemed to him entirely possible that it might be due to the original poison causing the disease, the delay in its appearance being, perhaps, attributable to the comparatively long time which it takes for such toxic agents to act upon the nervous system.

In concluding the discussion, DR. THOMSON said that he had purposely refrained from taking up the subject of heart-failure in the paper because it was one presenting so many complications. He doubted very much, however, whether it were due to the same cause as the late paralyses. In many cases he believed that myo-carditis was present, and it seemed to be altogether probable that this was the fact in Dr. McLean's case. He had not touched upon the matter of therapeutics in the paper, but he quite agreed with Dr. McLean that electricity was of no value. It was highly desirable to stimulate the peripheral extremities of the nerves, and this could be best accomplished by applying to the throat in palatine and pharyngeal paralysis a paste made of equal parts of honey and black pepper. In paralysis of the extremities or trunk, an infusion of red pepper (a drachm to the pint) was also a useful local application, the parts to be enveloped in a pack of this kind twice a day. As to Dr. Putzel's criticism in regard to the post-latent period of diphtheria, it seemed to him that the paralysis was an indication of processes going on subsequently to the acute stage, and that this post-latent stage was a general characteristic of all the acute fevers. The post-latent stage varied in its manifestations in the different diseases, and, as he had stated in the paper, it was highly probable that the phenomena noted in diphtheritic paralysis at least were due to the agency of a ptomaine.

THE BOSTON Medical and Surgical Journal.

THURSDAY, JUNE 14, 1888.

A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 94 Boylston Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 94 Boylston Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES AND HURD,
94 BOYLSTON STREET, BOSTON, MASS.

THE MASSACHUSETTS MEDICAL SOCIETY.

As we go to press the annual meeting of the Massachusetts Medical Society is still in progress, and appears to be a meeting of more than average interest. It is somewhat remarkable that two attacks should be made at the same moment upon the condition of perfect freedom in the practice of medicine which exists in Massachusetts. The annual address is outspoken in its words in regard to the tolerance in this community of men of pretensions to knowledge in medicine derived from other sources than education, a tolerance which exists to a certain extent among men who are far from trusting to humbug of any sort in any other matters. The JOURNAL is happy in being able to assist the daily papers in their efforts to give the address a publicity among an audience of non-medical readers, because it will assist undoubtedly some of those who may read it to a better understanding of the way in which the profession regards the uneducated practitioner.

The Society is fortunate in its choice for president of Dr. D. W. Cheever, the esteemed professor of surgery of the Harvard Medical School.

ALCOHOLIC PARALYSIS.

In the *American Journal of Medical Sciences* for June, 1888, are two articles on alcoholic paralysis, one by Dr. C. W. Suckling, of London, the other by Dr. Byron Bramwell, of Edinburgh. Both agree as to the pathology; the lesion of the nervous system associated with this paralysis being a multiple peripheral neuritis. Sensory disturbances such as myalgic pains, muscular tenderness and hyperaesthesia of the skin are marked symptoms in the majority of cases. Some cases are characterized by a wide-spread distribution of the paralysis, and the presence of well-marked nystagmus and paralytic weakness of the muscles of the eye-balls. The paralyzed parts are always flaccid

and atrophied; contracture may occur, but it is rare. The bladder and rectum are rarely implicated. The faradic irritability is usually diminished, and in severe cases it is entirely abolished, while the galvanic irritability is increased, and the contractions sluggish and prolonged, the reaction of degeneration being well-marked in bad cases. Vaso-motor changes are usually present, the extremities being red and sometimes oedematous, and occasionally presenting purpuric spots. The skin of the hands and feet is sometimes glossy, at others harsh and dry. The nails are frequently affected, being curved, rigid, opaque and brittle.

Mental symptoms are generally present; the memory is impaired, the patient is emotional, suffers from insomnia, dreams, restlessness, delirium and hebetude, together with digestive disturbances, such as morning sickness and retching. Such symptoms, says Suckling, occurring with ataxy or paralysis, render the diagnosis of the nature of these two symptoms tolerably certain.

The diagnosis is usually easy. The patient complains of pains, and loss of power in the legs, the feet are dropped and flaccid, and the toes cannot be pointed upwards. The grasp is feeble, but the upper extremities are often exempt from marked paralysis. Great pain is elicited if the calf-muscles are grasped, and there is tenderness along the nerve-trunks, and frequent cramps in the calf-muscles. The knee-jerk is absent; this might lead to a confounding of this disease with tabes, for loss of the knee jerk, pains and ataxy are present in both diseases, but the pupil-symptoms of tabes are not present in peripheral neuritis.

The prognosis is usually favorable, if the nature of the disease be detected early, and the cause removed. As for treatment, rest in bed is necessary; if there is much pain, hot fomentations and anodyne liniments are useful. Opium must be given with care. Cocaine may be injected subcutaneously. Rubbing is of great value. Strychnia is regarded by Suckling as an invaluable remedy. But in all cases, the absolute withdrawal of alcohol must be insisted upon, or the case will end fatally.

Bramwell's article is of especial value as embodying personal researches in the pathological anatomy of this affection, as well as numerous cuts giving the microscopical appearances which sections of the degenerated nerves in a typical case presented. In many instances the nerve-tubes are seen to be shrunken and atrophied (their axis cylinders and white substance of Schwann having completely disappeared), and are either completely empty, or contain a granular and molecular debris. The degenerative changes affected principally the posterior tibial and plantar nerves; the posterior tibial artery was also atheromatous. Bramwell was disposed to think that the nerve-changes were due to a peri-neuritis, and the pressure of the inflammatory products on the nerve-trunk.

ON THE USE OF CONCENTRATED LACTIC ACID AS A CAUSTIC.

IN the *Centralblatt für Chirurgie*, No. 12, 1885, Prof. Mosetig-Moorhof announced the discovery that of all caustics, lactic acid was the best for morbid growths, inasmuch as it had the property of selecting out diseased, and sparing healthy, tissue. Mosetig-Moorhof used this caustic in lupus, epitheliomata, fungous processes, papillomatous growths, etc., and recommended its employment in preference to curing.

For superficial application to ulcerating or carious surfaces, the pure, concentrated acid was used, being applied to the diseased part on absorbent cotton, and left on from six to twenty-four hours. After removing and washing, the part was allowed to rest a day or so, and then the application was renewed.

Since the publication of Mosetig-Moorhof's results with this agent, Joseph¹ has reported a case of *leucoplakia buccalis* cured with eighty per cent. diluted lactic acid, and Jellinek has given it a thorough trial in tuberculosis of the larynx. For this purpose he employs a twenty to eighty per cent. solution. The healthy mucous membrane, he says, is but slightly affected, while infiltrated portions are thoroughly destroyed. The more succulent the infiltration, the more vigorous the action; oedematous parts shrink in three or four days, and troubles in deglutition are rapidly relieved. In ulcerous, granular and hypertrophic pharyngitis, he has had good results. Jellinek believes that in laryngeal phthisis, by daily applications, more can be accomplished with this than with any other remedy, and that in its earlier stages this disease can thus be cured.²

Brün afterwards made trial of lactic acid in fungus, that is, tubercular disease of soft parts, and reports nineteen cases in patients from one to fifty-two years of age.³ The average number of acid dressings was three, and the average time of cure, twenty-five days. There were no failures, and up to date, six weeks to five months later, no relapses. He affirms that lactic acid will attack healthy as well as unhealthy epidermis, but in the subdermal tissue it seeks out fungous nests and destroys them.

Since these experiments were made, this caustic agent has been much used by practitioners the world over, and despite the favorable results often obtained in epithelioma and lupus, it is probable that the judgment of Spitzer and Hermann, formulated after a careful trial in eight cases, may be regarded as the judgment of the profession:

(1) The pain produced by the cauterization with lactic acid is at least as great as that caused by any other caustic. (2) The patients prefer invariably any caustic to lactic acid. (3) The action of lactic acid resembles that of other caustics, but is less energetic. (4) Healthy tissues are not spared by this any more

¹Dout. Med. Woch., No. 43, 1885.

²Therapeut. Gazette, 1886, p. 322.

³Therapeut. Gazette, loc. cit.

than by any other caustic. (5) Lactic acid has to be employed for a much longer time than chloride of zinc and other energetic caustics.

MEDICAL NOTES.

The annual meeting of the Councillors of the Massachusetts Medical Society took place Tuesday evening June 12th, at 19 Boylston Place, and resulted in the election of these officers for the Society for the ensuing year: President, David W. Cheever, Boston; Vice-President, George Jewett, Fitchburg; Corresponding Secretary, C. W. Swan, Boston; Recording Secretary, F. W. Goss, Boston; Treasurer, F. W. Draper, Boston; Librarian, E. H. Brigham, Boston; Orator, H. P. Walcott, Cambridge; Anniversary Chairman, J. R. Chadwick, Boston.

At the annual meeting of the Massachusetts Medical Society, which took place June 12th, the following officers were elected. President, Dr. J. G. Pinkham, of Lynn; Vice President, Dr. A. F. Holt, Cambridge; Corresponding Secretary, Dr. B. H. Hartwell, Ayer; Treasurer, Dr. C. C. Tower, South Weymouth; Recording Secretary, Dr. W. H. Taylor, New Bedford; Standing Committee, F. W. Draper, M.D., Boston; S. D. Presbrey, M.D., Taunton; F. Winsor, M.D., Winchester.

—In accordance with a resolution adopted by the Faculty of Medicine of the University of Pennsylvania, the first number of *The University Medical Magazine* will be issued October 1, 1888, to be edited under the auspices of the Alumni and Faculty of Medicine of the University of Pennsylvania. It will contain original articles and clinical lectures by members of the Faculty, clinical professors, demonstrators, and instructors, and will represent their teaching and practice in the various hospitals with which they are associated.

—The *Medical Record* quotes from a publication by the Gotha Life Assurance Bank, some statistics of the mortality among its policy-holders during 1887. From these it appears that the mortality of the medical members was 11.53 per cent. above the average of that of all the members taken together. The classes of disease to which this higher rate of mortality was due, were diseases of the respiratory organs, phthisis, and infectious diseases — “typhus” having proved especially fatal to the younger members of the profession. There was only one case of post-mortem poisoning, out of 1,052 deaths, and that was of a district physician. Cerebral apoplexy was remarkably frequent, beginning as early as thirty-six years of age. There were fourteen cases of suicide, and four of accidental death. These are, however, below the general average.

NEW YORK.

The first International Congress of Anthropology to meet in this country held its sessions during the

past week at Columbia College, under the auspices of the New York Academy of Anthropology, with Dr. Edward C. Mann, President, and Dr. H. S. Drayton, Secretary. Among the visitors from abroad who took part in the proceedings was Prince Roland Bonaparte, who was the recipient of much attention. Dr. Henry Maudsley, of London, sent a paper, which was read by the Secretary, on “Criminal Anthropology, Criminal Biology and Sociology, Crime and Criminals,” in which he protests against the growing disposition in some quarters to look upon every criminal as of unsound mind, and to discover distinct evidences of criminal nature in the conformation of the head and face, and in the defective structure of the brain. “A cursory survey of criminals,” he said, “suffices to show that they fall at once into two very distinct classes, the one comprising what may be called the occasional or accidental criminals, and the other what may be termed the natural and essential criminals. The occasional criminal will not present in form, feature, or cerebral structure anything characteristic to distinguish him from persons who have not been convicted of crime. Some men fall deeper and deeper into crime, while others remain honest because of the absence of similar temptations under similar circumstances. . . . The essential criminal is one who is so by reason of defective mental organization. Most often the defect is of the nature of intellectual and moral weakness, which, being irremediable, lands its victims in the class of habitual criminals. A third very distinct group of offenders against criminal law comprises those who break it while laboring under positive disease. To this class belong such law-breakers as the general paralytic, the epileptic, the maniac, and those suffering from melancholia. There is no general criminal constitution, predisposing to and excusing crime, and there are no theories of criminal anthropology so well grounded and exact as to justify their introduction into revised criminal laws. The time has come when we ought to use our prisons as we do our hospitals, not for the care and treatment of the inmates only, but for the advancement of knowledge and the improvement of man's state. So doing, we may hope to make a useful contribution to the building up of an individual psychology, which, although of humble origin and modest pretensions, shall grow vigorously, and eventually displace the barren disquisitions and speculative theories that, usurping the name of psychology, have not been, nor ever can be, of the least practical use to mankind, either in the breeding of children, the guidance of education, or in the conduct of life.”

Among the other papers read were the following: “Mental Automatism,” by Prof. E. P. Thwing, of Brooklyn, in which he gave an exposition of hypnotism, and argued in favor of its practical uses; “The Transmission of Deformities through Three Generations,” by Dr. M. L. Holbrook, of New York; “The Ethnography of the Hawaiians,” by Dr. Titus Munson Coan, formerly of the Sandwich Islands; “The

Coming Man: a Dietetic Problem," by Dr. Frank Woodbury, of Philadelphia; "Psychological Heredity," by Dr. T. D. Crothers, of Hartford; and "Pathological Inebriate Heredity," by Dr. Norman Kerr, President of the Society for the Study of Inebriety in London, and Chairman of the Legislative Committee of the British Medical Association. In his paper, which was read by Dr. Lewis D. Mason, of Brooklyn, Dr. Kerr states that no inconsiderable proportion of criminal deeds, committed by individuals under the influence of stimulants or narcotics, is the outcome of physical disease, as shown by modern scientific study. If this prior diseased condition had been treated and rectified, many acts of inebriate folly, vice, and violence would never have been perpetrated. The craving for narcotics, "narcomania," he said, was a disease which might be either acquired or inherited, and heredity, he claimed, was the most potent of the causes predisposing to inebriety. The results of investigation had been such that, while he could not go so far as to agree with the claims that from sixty to eighty per cent. of all inebriates inherited their craving for intoxicants, he was convinced that fully one-half suffered from the hereditary taint. These might be divided into direct and indirect inheritors. In the latter there might be an innate tendency to excess, so that such handicapped inheritors of the inebriate diathesis were utterly unable to indulge in moderation. In such cases there might be no craving for liquor — there might even be a distaste for it — but there was, nevertheless, a resistless impulse toward it from birth, a proclivity so strong that the slightest indulgence precipitated the subject into a paroxysm of inebriate excess. In other cases there seemed to be an actual parental craving for intoxicants, inherited from conception, and the subject indulged with avidity. In both the direct and indirect forms he had known the traits of drunkenness to be exhibited as early as from the third to the sixth year. The pathology of the inherited drunk impulse consisted in maternal nutrient perversions of the fetus during pregnancy.

Among the papers read on the last day of the Congress was one by the President, Dr. Edward C. Mann, on "The Physiological Action of Alcohol"; and one by Dr. Nelson Sizer, of New York, on "The African: His Face and Cranium Considered in Relation to Industry, Skill and Economy in his Normal State, and the Effect of Caucasian Influence on his Facial and Cranial Development."

— At a meeting of the Academy of Medicine, held June 7th, Dr. T. Gaillard Thomas read a memorial paper on the late Dr. Cornelius R. Agnew, and the Building Fund Committee presented its report. This was read by Dr. Alfred L. Loomis, who stated that in addition to the \$100,000 received from Mrs. Woerishoffer, and the estates of the late Drs. Hosack and Beadle, \$11,995 had been received in response to the circulars sent out by the committee asking for subscriptions to the fund.

— The governor has signed the bill substituting death by electricity for hanging in the case of all criminals condemned to death, which was passed by the recent Legislature; and New York will thus have the honor of being the first State to abolish hanging in cases where the death penalty is ordered by law. It will be remembered that this bill consists of a number of carefully prepared amendments to the code of criminal procedure which provide that the prisoner sentenced to death shall be immediately conveyed by the sheriff to one of the State prisons, and there kept in solitary confinement until the day of execution, in the meanwhile to be visited only by officers or by his physician, clergyman or counsel; that the court imposing sentence shall name merely the week within which the execution is to take place, the particular day in such week being left to the discretion of the principal officer of the prison, and that the execution shall be practically private, only officials, clergymen, physicians, and a limited number of citizens being allowed to be present. The revolting scenes which have characterized so many public executions in the past can, therefore, be no longer repeated; and the doing away of the publicity which has hitherto attended executions will, it is believed, constitute a very salutary reform.

— Dr. Peters has explained that while the action taken at its last meeting by the County Medical Society in reference to the condition of the Croton water supply was in some respects sudden, it was not intended to arouse any sensation or scare in the public mind. The Society, he said, simply desired to start necessary steps for securing the purity of the water in the future. The meeting was the last one before September, and the Society decided to apply to the Senate investigating committee, appointed this session of the Legislature, to inquire into the whole subject of Croton water and the building of the new aqueduct. The Board of Health, Dr. Peters thinks, should adopt the system of microscopical examination of suspected water, as being more thorough and satisfactory than the system of merely chemical analysis at present employed.

— The coroner's jury which was for more than two weeks engaged in investigating the killing of a lineman of the Brush Electric Illuminating Company, has rendered a verdict, founded on the testimony of many expert witnesses, which hold the company responsible for the man's death. It finds that his death was caused by an electric shock received from an improperly insulated electric-light wire, while he was in the discharge of duty as a lineman, and strongly condemns the parsimonious spirit of the electric-light companies in maintaining a constant menace to life and property by not keeping their wires in repair with proper methods of insulation. The jury also recommends that the coroner shall immediately call the attention of the district attorney to the illegal maintenance of wires above ground in the city of New York.

RESOLUTIONS ON THE DEATH OF DR. EDWARD S. DUNSTER.

Resolutions passed by the Wayne County Medical Society, Detroit, May 4, 1888.

Whereas, it has pleased Almighty God to remove from this earthly sphere our worthy companion and professional brother, Dr. Edward S. Dunster, of Ann Arbor, Mich., therefore, be it

Resolved, that we as a Society, tender to his grief-stricken family our heart-felt sympathies.

To the profession before whom he has appeared so eloquent in address, logical in his reasoning, honest in his opinions which he maintained with his utmost power, and above all, his loyalty to his profession he so dearly loved, and for whose best in-

terests he so long and sedulously labored, we can only say that the loss of one so eminent can ill be told in resolutions or words; in this the heart alone can speak.

Is obedience to the Almighty power that rules the destinies of men, that can build up or cast down, that can give or take away, we bow in humble submission about the bier of our departed friend, fellow-member and professional brother. Be it further

Resolved, That our Secretary transmit a copy of these resolutions to the press and to the family.

WM. BRODIE, M.D.
HAL C. WYMAN, M.D. } Committee.
C. HENRI LEONARD, M.D.

Deaths reported 1,896; under five years of age 736; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhœal diseases, whooping-cough, erysipelas and fevers) 320, consumption 266, acute lung diseases 217, diphtheria and croup 206, diarrhœal diseases 55, scarlet fever 41, measles 30, typhoid fever 25, cerebro-spinal meningitis 13, whooping-cough 13, erysipelas 12, malarial fever 10, puerperal fever eight, small-pox seven. From measles, New York 19, Pittsburgh three, Boston, District of Columbia and Springfield two each, Baltimore and Newburyport one each. From typhoid fever, Philadelphia 11, New York six, Baltimore, Boston, District of Columbia, Pittsburgh, Worcester, Cambridge, Fall River and Lynn one each. From cerebro-spinal meningitis, New York, Nashville, Fall River and Salem two each, Philadelphia, Baltimore, Boston, District of Columbia and Mahlen one each. From whooping-cough, New Orleans six, New York five, Boston and Pittsburgh one each. From erysipelas, New York four, Boston three, Philadelphia two, New Orleans, Nashville and Worcester one each. From malarial fever, District of Columbia four, New York and Baltimore two each, Philadelphia and Charleston one each. From puerperal fever, New Orleans four, Milwaukee two, Boston and Springfield one each. From small-pox, New York and Philadelphia three each, Boston one.

OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JUNE 9, 1888.

MAGRUDER, A. F., surgeon. Detached from the "Yantic" and granted sick leave.

BATES, N. L., medical inspector. Ordered to the "Richmond."

KIDDER, B. F., medical inspector. Detached from the "Richmond" and wait orders.

MACKIE, B. F., surgeon. Detached from Naval Examining Board, preparatory to sea service.

HEYL, T. C., surgeon. Ordered to the Receiving-ship "St. Louis."

STREETS, T. H., surgeon. From "St. Louis" and to Medical Examining Board as recorder.

DEBEYSE, W. R., passed assistant surgeon. From Naval Hospital, Norfolk, and to the "Jamestown."

WELLS, HOWARD, passed assistant surgeon. From the "Jamestown" and to Naval Hospital, Chelsea.

The meteorological record for the week ending June 2, in Boston, was as follows, according to observations furnished by Sergeant J. W. Smith, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.		Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.	7.00 A. M.	3.00 P. M.	10.00 P. M.

OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING JUNE 9, 1888.

BAIDACHE, P. H., surgeon. Detailed as Chairman, Board of Examiners, to meet in Washington, June 25, 1888. June 8, 1888.

FESSENDEN, C. S. D., surgeon. Detailed as member, Board of Examiners, to meet in Washington, June 25, 1888. June 8, 1888.

PERVANCE, GEORGE, surgeon. Detailed as recorder, Board of Examiners, to meet in Washington, June 25, 1888. June 8, 1888.

SOCIETY NOTICES.

THE CONGRESS OF AMERICAN PHYSICIANS AND SURGEONS.—Preliminary Programme of the Fifth Annual Meeting of the American Climatological Association, Washington, D. C., September 18, 19, and 20, 1888. The following papers and discussions have been arranged for, and others may be added to the list:

The President's Address, Dr. A. L. Loomis, New York. The Relation of High Altitudes to Germ Diseases, Dr. S. A. Fisk, Colorado. Is Climate an Etiological Factor in Graves' Disease, Dr. R. G. Curtin, Philadelphia. An Environment Experiment Reported, Dr. E. L. Trudeau, Saranac Lake. Definite Results Obtained by the Climatue Treatment of Disease, Dr. A. Y. P. Garnett, Washington. Invalids Suited for Treatment at Colorado Springs, Dr. S. E. Solly, Colorado. Influence of Semi-Tropical Latitudes on Types of Disease, Dr. Jno. Gutierrez, Charleston. Discussion of the Relative Importance of Different Climatic Elements in Treatment of Phthisis, *Referee*, Dr. E. T. Bruen, Philadelphia; *Co-Referee*, Dr. V. Y. Bowditch, Boston. Observations on the Use of Terebene, Dr. D. M. Cammann, New York. Climate and Bright's Disease, Dr. J. C. Wilson, Philadelphia. Discussion of The Mineral Waters of the United States: Therapeutic Value as Suggested by their Chemical Composition, Dr. A. C. Peale, Washington; Their Therapeutic Value in Gastro-Hepatic Diseases, Dr. William Pepper, Philadelphia; Their Therapeutic Value in Urinary and Arthritic Diseases, Dr. A. H. Smith, New York; Their Therapeutic Value in Malarial Diseases, Dr. J. C. Van Bibber, Baltimore. Report on Mineral Springs, Dr. C. C. Rice, Chairman, New York. Interrelated Pathological Products, their Cause, Significance, and Special Relationship to Pulmonary Phthisis, Dr. J. R. Leaming, New York. Conditions which tend to Render the Atmosphere of a Locality Aseptic, J. T. Whitaker, Cincinnati. Discussion of the Influence of Altitude on Cardiac and Pulmonary Diseases, *Referee*, Dr. P. Donaldson, Sr., Baltimore; *Co-Referee*, Dr. J. F. Lovick, Philadelphia. Climatic Characteristics of Texas, Dr. Morse K. Fay, U. S. A., San Antonio. Therapeutic Differences of Mountain and Sea Air, Dr. W. H. Geddings, Aiken. Indications and Contra-Indications for Altitude in Treatment of Phthisis, Dr. F. I. Knight, Boston. Discussion of the Nasal and Neurotic Factors in Etiology of Asthma, *Referee*, Dr. F. E. L. Bosworth, New York; *Co-Referee*, Dr. E. L. Shury, Detroit. Therapy of Climate, Dr. I. H. Platt, Lakewood. Therapy of Ocean Climate, Dr. A. L. Gihon, U. S. N. Climatic Characteristics of Roan Mountain, Eastern Tennessee, C. J. Kenworthy, Florida. Notes of Summer in Switzerland, Dr. D. B. St. John Roosa, New York. An Epidemic of Cerebro-Spinal Meningitis in Central New York, Dr. W. T. Ford, Utica. Further Contribution to the Study of Consumption among the Indians, Dr. W. Matthews, U. S. A.

A. L. LOOMIS, M.D., LL.D., President.
J. B. WALKER, M.D., Secretary.

AMERICAN LARYNGOLOGICAL ASSOCIATION.—The Preliminary Programme of the Tenth Annual Congress which will be held in Washington, D. C., September 18, 19, and 20, 1888, is as follows:

Ten Years of Laryngology, Rufus P. Lincoln, M.D., New York. Congenital Bony Occlusion of the Posterior Nares, Chas. H. Knight, M.D., New York. The Effects of varying rates of Stimulation on the Action of the Recurrent Laryngeal Nerves, Franklin H. Hooper, M.D., Boston. Subglottic Laryngeal Enchondroma, E. Fletcher Ingals, M.D., Chicago. A Photographic Study of the Laryngeal Image during the Formation of the Registers, and Production of Variations in the Pitch of the Singing Voice, Thomas R. French, M.D., Brooklyn. Lapsus of the Nose, Pharynx and Larynx, Samuel Johnston, M.D., Baltimore. Inguinary Lingual Ulceration, George M. Lefferts, M.D., New York. A Possible Substitute for Tracheotomy and Intubation in certain cases, Edgar Holden, M.D., New York. Antiseptic Nasal Surgery, Clarence C. Rice, M.D., New York. A Case of Sarcoma of the Tonsil, Alexander W. MacCoy, M.D., Philadelphia. A Case of Subglottic Chronic Stenosis of the Larynx cured by Dilatation, Frank Donaldson, M.D., Baltimore. Internal Esophagotomy, John O. Kee, M.D., Rochester. The Treatment of Atrophic Rhinitis by the Galvanic Current, J. H. Hartman, M.D., Baltimore. The Anatomy of the Nasal Chambers, Harrison Allen, M.D., Philadelphia. Notes on a Case of Nasal Caries, complicated with Meningitis; successfully treated by means of the Surgical Drill, Wm. C. Jarvis, M.D., New York. On Fixation of one or both Vocal Bands in the Pharyngeal Position. (So-called Abductor Paralysis), P. Donaldson, Jr., M.D., Baltimore. Residence at Certain High Altitudes as a Means of Cure for Laryngeal Phthisis, Clinton Wagner, M.D., New York. Further Investigations as to the Existence of a Cortical Motor Centre for the Human Larynx, Dr. Bryson Delavan, M.D., New York.

Besides the above titles which have been received to date, papers have been promised by Drs. Morris J. Ash, J. Solis Cohn, John N. Mackenzie, and Beverly Robinson; and by Dr. A. Gougenheim, of Paris. A number have yet to be heard from.

D. BRYSON DELAVAN, Secretary.

1 East 53d Street, N. Y.

BOOKS AND PAMPHLETS RECEIVED.

Vesico-Vaginal Fistula. By Reuben A. Vance, M.D. Cleveland, O. Reprint. 1888.

The Neural and Psycho-Neural Factor in Gynaeciac Disease. By C. H. Hughes, M.D., St. Louis, late Superintendent Missouri State Lunatic Asylum; Honorary Member British Medical-Psychological Association, etc. St. Louis, Reprint. 1888.

L'Atrofia e Litofalassia. Per il Dr. Gustavo Usiglio, già Operatore nella Clinica del Prof. Billroth a Vienna, I. Chirurgo assistente nell'Ospedale Civico di Trieste. II Edizione. Trieste. 1888.

Annual Report of the Provost of the University of Pennsylvania, including Reports of Departments and Abstract of the Treasurer's Report, for the Year ending October 1, 1887. 1888.

Station-List of Officers of the Medical Department and Hospital Stewards of the Hospital Corps, United States Army, April 1, 1888, or at date of last report received at this office. Washington.

The Intra-Uterine Stem in the Treatment of Flexions. By A. Reeves Jackson, A.M., M.D., Professor of Gynaecology in the College of Physicians and Surgeons of Chicago; Fellow of the American Gynecological Society, etc. Reprint. 1887.

Address.

RE-ESTABLISHMENT OF THE MEDICAL PROFESSION.¹

BY E. JOY JEFFRIES, A.M., M.D., OF BOSTON.

OUR profession cannot contend with what is called business in the accumulation of wealth. No man ever made a fortune as a physician. I mean no one ever paid his expenses and laid by at interest enough to live on, through the practice of medicine. I do not, of course, refer to those who have entered into business with their gains, by speculation or speculative investments. Such may have gained or lost as other so-called business men do. This we have in common with the other professions, though we are not so well positioned as they as we advance in life. Even with continued health and strength, and the largest possible amount of practice, a physician in this country can never acquire by his toil the incomes readily made in other occupations now recognized as professions. Moreover, many of these place a man in direct opportunity to become profitably interested in business enterprises, more or less associated with his special work.

It is therefore useless for us to contend with trade or business either in earning a living or in the accumulation of money. Our profession is most essentially not a trade. Those in it who attempt to make it so but lower themselves to the level of trade, or simply money-making. Our calling belongs to that department of man's work recognized as scientific or knowledge seeking. We are simply men of science, that is, men of knowledge and its pursuit, the attainment of which is to benefit other people primarily. Now the world over, men who give themselves up to the pursuit of knowledge have been considered as worthy of only so much of this world's goods as will simply keep them bodily in a condition to work with their brains and hands in science seeking.

When these other professional men apply science, knowledge, to the useful arts, that is, render money-making possible, then their recompense may be very large. But the physician's science or knowledge is applicable only to relief of pain, the saving of life, or the increased healthfulness and bodily comfort of mankind. This the world does not similarly recompense. The world at large values knowledge only as a means of making money. I say the world at large; fortunately for mankind there is a body of truth seekers for truth's sake. To this class our profession should belong. And we deserve recognition in it because we do not keep what we learn, but disseminate our knowledge as quickly as possible for the benefit of humanity. True, this humanity or the world at large simply regard us as fools for so doing. But the diligent study and the honest practice of medicine gives a man a power, and a self-respect, and a consuming interest, a love of his profession which lifts him above the assaults of the world. The physician has a contentment which aggravates as well as surprises those he comes in contact with. In this contentment we understand and hold by each other as kindred spirits.

No class in the community know better than phy-

sicians the baneful effect of what in general terms is called "filthy literature." Here our knowledge is of value, and our opinions will be received by the community. Have we not dreaded giving them from disgust at cant, pseudo-morality and false sentiment?

But there are associated together for the suppression of vice, good, honest, mentally strong, shrewd and prudent men and women, who have in their work to contend with the best paying criminal rascality and foulness existing among us. Money will flow like water to prevent legislative control. Are we as physicians, knowing and seeing all, doing our share in helping those properly at work for the suppression of vice? There can be no false stigma attached to any professional efforts of the kind.

Certainly one thing we should do; namely, by united action and condemnation, prevent medical book notices from being distributed, containing wood cuts, often perhaps totally unnecessary in the books themselves, and which in the pamphlet advertisements never induced the rightful sale of a single copy.

The respect of the old due to the young—I do not think anywhere in life this applies more strongly than in our profession. The young have first what time and the wear and tear of life slowly but surely eat away, namely, enthusiasm. Without this but little can be accomplished, and that little only as a burden. The young have that power of adapting themselves to new or changing circumstances which old men have not, and progress in our profession means just this. Capacity for work, both physical and mental, exists in the young that the old no longer possess, or but very exceptionally, and only to prove the rule.

A man has had thorough preliminary instruction in youth, and subsequent professional education of the best. He has talent and ability, and knows how to use these. He is urged for some place of trust and influence for which he is well qualified. "Don't you think he is rather young?" is heard from some over-prudent objector. No, I want to reply, but your saying so proves that you are already too old to retain your place. Respect for the young is prudence as well as justice.

How many years ago would it have been rank heresy to have urged any one under sixty years of age for the presidency of the then *Harvard College*, but the *university* has been built up by such an one, and not least the department we are interested in. Our Society should reverse the maxim, young men for action, old men for councillors.

What! would you throw away the value and weight of experience? Certainly not, if the latter had any knowledge to start with, and the power and ability to constantly accumulate further, and to impart it. Merely having lived or practiced so long does not necessitate the increase of knowledge or a greater power of its application. Quite the reverse,—it may have simply frittered away originality by dull routine. Inexperience is often of real value, because it dares to do and try what experience has shown some one else *he* cannot do. Years of accumulated sameness is only worthy of the respect which age alone gives. Mere time does not make valuable experience; the latter comes from constant and progressive thought and study, and their intelligent application to professional life

¹ The annual address to the Massachusetts Medical Society, June 13, 1888. Concluded from page 593.

and work. Experience may or may not come with age; the latter does not of itself make it. This is one of the greatest fallacies of the present age in all departments of life.

Old age is to be respected for itself, but when it would guide our actions by its experience we demand to know what that has been, and of how great value. Age as well as youth must prove its ability to have observed and drawn truthful conclusions; that is, to have advanced by intelligent study. Time does not make solid ignorance knowledge. But how eagerly the world seeks the experience of those who have proved themselves capable of having profited by it. The fancied accumulation of knowledge from the mere lapse of time is a dangerous mistake.

I often recall the following instance. In the Director's room of a railroad corporation I had shown the officials the practical results of defective color-sense by instances from among their employes. They could not or would not understand or admit it. One otherwise pleasant old gentleman sank back in his arm-chair, and with almost a snarl of doubt and derision exclaimed, "Why, Dr. Jeffries, I have been railroading more than forty years, now if any such thing as color-blindness existed, I must know all about it." And how far is the community from this now?

Education is the teaching the hands to work at advantage and the brain to think rightly. Certainly this applies to medical education. Proper medical education cannot be given the ignorant young man, and only young men should be made doctors. If the hands and brain have not been trained how to work, they cannot be properly employed in the higher field of human activity occupied by the physician. The advance in modern education comes not from additional amount of facts poured into the school boy or student, but from applying improved systems by which brain work tells better.

It is possible to teach the power of observation, deduction, the application of principles, and sharpen the brain, the wits, to seize the time for action. The medical schools admitting young men without such preparation, even if they attempt to teach well and thoroughly, never can turn out the best physicians.

The young man in this country who wants to go into medical trade thinks he has only to learn a little and get his diploma as he would fit up a grocery shop. The community thinks so too. The so-called medical colleges scattered over the country are ready to help him for the fees he can scrape together to pay them. This tradesman opens his shop for custom, and the world looks upon and patronizes it like any other shop. But in medicine as in all the true professions, work but commences with the responsibility of occupation, and never ceases while that lasts. Better for a man if it lasts through his life.

Now these medical colleges, backed by the community, want the profession to foster such trade doctors, and have us accept them as colleagues. These men themselves claim our support and recognition, and would pull us down to their level to help their trade. The time has amply come for this to stop. The physician must rest on his individuality, on his learning and his power of using his knowledge.

If you carefully observe the men teaching and

learning in this and the two adjacent buildings,² and then compare them with the men teaching and learning in the building farther on, in which we are or should be all interested, there will be found a difference of a peculiar and subtle character, the difference between the medical and the technical man. Perhaps only our profession can understand this. I have found very shrewd men in the other professions, even the allied ones, much puzzled by it.

Here in technology, arts, sciences aside from us, the students learn facts, physical laws, principles, and their adaptation to physical conditions, and relies on set and fixed laws and rules for action. His work in life is a continuation of this. Here two and two make four, and can always be depended on as making four, mathematically deducible and proved as we say.

Now in the other building the medical student learns also facts, physical laws and natural principles. But in practice he has to apply them to unnatural conditions, disease. And he learns that the conditions of disease render mathematical application of seemingly fixed principles impossible. Two and two may not make four, and he must be able to grasp this fact. The study of medicine is for this, and four years is little time enough to learn the needed facts, their application, and so to speak misapplication. This it is which besides all else separates us from other professions, and but puzzles them. They see us arriving at results from data that their knowledge and experience prove mathematically can not come. This elusive something is the spirit of medicine; he who has it most will most successfully be able to detect and cope with disease, be the most successful physician. I do not mean as to the number of his clients. That is no proof of medical talent. It is, in fact, in this country, more generally a proof of its absence. The pretender and the quack have the largest number of applicants for a time, till the next quack comes.

Since the slavery rebellion our nation has settled down to its civilization. Has our profession advanced with increasing education? Not the whole of it, for the reasons I have given. But there are many more men than ever before giving their strength and lives to the accumulation of knowledge in our calling, and its diffusion. Never before have there been so many men so highly educated in medicine as now. I cite as proof, the papers and discussions at our Society meetings, the articles published in our journals, the respect our best men are gaining from the thorough medical scholars and teachers of England and the Continent. I cite further the greatly increasing number of physicians in the various branches of medicine who are becoming good and valuable teachers among us. Never before have we had such competent and thoroughly taught practitioners under thirty years of age. Never before have we had so much true scientific work going on in our profession. The graduates of even our best schools are not content to stop their work, but seek in Europe the best teachers to compare their acquirements, and bring back to us the highest medical culture of the old centres of learning.

Should these men be classed with the ill-bred and half-educated graduates of the remaining nine-tenths of the medical schools of this country? Because they have the same title, must they be put on the same plane as the business and trade doctors our communi-

² Buildings of the Institute of Technology and Natural History Society.

ties are overrun with? Yet this is precisely the way they are at present treated and regarded by the laity, who make no distinction between one physician and another. And this by all classes of the laity, high and low, rich and poor, learned and unlearned.

The scientific man is often now startled by finding "a doctor" familiar with his own department. It is quite a revelation to him. Why, nearly all the work in the various sciences outside ours, now followed as professions, was formerly done by men graduates in medicine!

Among us and in our Society, this advance in medical education has been brought about by the thorough and complete change in the plan of teaching and instruction of our University School, the raising the standard of requirement, and the absolute refusal to grant a diploma of Harvard to any graduate who falls below such standard. Moreover, this elevation of the profession has been helped by the Massachusetts Medical Society also raising its standard of requirement. This is by no means so easy a thing to accomplish. The School is strong enough to be independent and insist on a proved preparatory education before entering on its curriculum. Our Society can at present only insist, by increased severity of examination, on greater medical attainments.

But it can do much to support our School and its teachers in their position by letting it be understood, and acting on the declaration, that to enter our ranks, the applicant must equal the Harvard graduate. The laity have no conception of the character of the teaching of our School. Have all the profession, all the members of this Society, a knowledge of its work and standing?

The most learned and scientific men in other departments have, I believe, but little if any knowledge of what this branch of the University and the very few other schools of similar standing in the United States are doing for the world. I regret that there are those, to whom to give this my judgment and words force and truth, I must say, as did the first president of the Suffolk District Medical Society,² when in his annual address eight-and-thirty years ago he praised the "Boston Medical School," "I do not utter this under the pressure of the official toga which I have never worn; but I record it as the tribute of a grateful pupil."

Having said this, I am free to ask, is our School and others like it doing *all* needed to fit men to practise medicine, to use their hands and brains professionally? The success and the growing number of polyclinics and post-graduate courses, right among our best schools, seem to me to positively prove that the student and the graduate find there is something more to be learned, and something worth giving time and money for. What better argument for the need of an additional year's study, however this may have to be arranged in reference to the undergraduate department of our universities and colleges?

If there are men who can as teachers attract earnest students outside of the regular courses, I do not see why they cannot be employed as teachers in the schools of four years' curriculum. This extra outside teaching I think has hindered the adoption of a four years' course as compulsory. It has fostered, unfortunately, the worst form of trade doctors among us; namely, the "two to six weeks'" fully-fledged specialist with any "scope."

I disregard the objection to four years on the score of cost. The men who built our present medical school did not stop for this sort of objection, and time has proved them right. I record here my conviction, and I wish I could record the conviction of this Society, in the support of the teachers and workers trying to elevate the standard of the profession, and thus, for only thus can it be done, replacing our calling in the respect of the laity, at the same time completely separating us in their judgment from the bands of quacks, trade doctors *et id genus omne*.

There is not in medicine the same danger of the teacher becoming the pedagogue as in general education. But I have suffered and seen others suffer so much from the latter that I cannot help giving a warning word. Medical teachers hold the same sort of relation as do other educators. They must not be too sensitive to the push and prod of the students and assistants in the struggle for existence. This should but keep them up to their work, as do the whole corps of young assistants the professors in Europe, whose places some of the former must finally fill. A man must wear his spurs after he has won them. Remember the respect of the old due to the young.

It is perhaps naturally expected of me here to say something in favor of those much *used* and much abused physicians called specialists. Whatever may be said against them, it must be admitted in candor that to stop the work they are doing would check the scientific advancement of the profession as a whole. Specialism means work, seeking science, knowledge, truth. It cannot be said that they keep from the profession or the world the results or benefits of their labors.

The same is now unfortunately true of the specialties as of the general profession. All I have said as to the laity's inability to distinguish between the true and the false applies with ten-fold force as to specialists. Physicians recognize this even in their own inability to decide between pretence and talent, knowledge and ignorance, experienced training and assumed.

I greatly respect other specialties, and cannot see how we can get along without them. I have to thank the men of talent and standing practising them, and have always found them as willing to help me as I them. They can defend themselves better than I can. Of my own I will say but a word. A foreign body in the cornea cannot be *prayed* out or *pried* out. The first our patient's wife has probably urged, the second been tried by a fellow workman, or the nearest doctor. But a drop of cocaine, a lens, a rightly shaped and sharp needle in a steady hand, directed by an experienced eye, quickly relieves our patient of his foe and fee. This is specialism, and as such is likely to remain among us.

It was said in praise of a physician who died some years ago that he was never seen in any place his profession did not call him. It was a proof of devotedness to his calling. In the then relations of the doctor to the community perhaps it was wise and necessary. All that has certainly passed away never to return. We are now forced to be *en rapport* with the world, its people and affairs, and, I believe, with a gain thereby to our usefulness in the practice of our profession. The more a man knows outside of and in

² The author's father, Dr. John Jeffries.

addition to his medical work, the better physician will be he. Such knowledge will never hurt his professional judgment, and will very often give him thereby a better opportunity to enforce what he knows to be necessary.

When a patient finds that we are by no means ignorant of his special work or business, can express an intelligent opinion thereon and have some interest in it, then that patient is nowadays much more likely to respect our professional advice and follow it. We have to guide and govern men and women, and we cannot without respect from the governed.
